Data Warehouse v.2.0 - Documentation

June 2026

Salvatore Morelli
Ignacio Flores
Luca Giangregorio
Demetrio Guzzardi
Jan Mazza
Francesca Subioli
Matteo Targa
Irene Toma
Severin Rapp

Authorship Note. This documentation file is the result of a collaborative effort supervised by Salvatore Morelli, the director of the Wealth Project, who conceived and designed the overall research project. Different subgroups were responsible for specific sections within the documentation and the appendices. Ignacio Flores was responsible for the overall data warehouse architecture, including the sections about Supplementary Variables, the data source classification, and citation reference organization. Matteo Targa oversaw the Wealth Inequality section, including the appendix tables documenting the treatment and classification of each data source. Iren Toma supported the Matteo's work and was responsible for the addition of the new ownership rate subsection, expanding the coverage using cross-national survey data among low and middle income countries. Jan Mazza and Severin Rapp led the Wealth Topography section, including the appendix tables outlining the composition rules and methodological choices for each source in the database. Francesca Subioli and Luca Giangregorio jointly oversaw the Taxes on Wealth section, including the classification of concepts used in the database and the corresponding appendix section. Demetrio Guzzardi led the new section of Inheritance Trends, structuring data, classifying and describing the new concepts within the data warehouse.

Acknowledgements, from GC Wealth Project Director Salvatore Morelli

The project was launched in June 2023 after approximately five years of development. This version of the data warehouse is launched in the Fall 2024. Many individuals contributed to varying degrees, during multiple stages, and to different sections of the project. First, the project would not exist without the continuous, reliable, and professional support of the Stone Center, including its director Janet Gornick, and the staff, Carolyn Fisher, Mei-Ling Israel, Jennifer Kitses, Veronica Ordaz, and Saraya McPherson. I also acknowledge the support from the Law Department of the University of Roma Tre, including the current director Antonio Carratta, as well as the admin staff Giuseppina Santilli and Federico Melograno. The communication support from Ylenia Sina is also acknowledged.

A number of people provided valuable feedback on a number of aspects during the early stages of the project. I particular, I am grateful to Facundo Alvaredo, Charlotte Bartels, Yonatan Berman, Miles Corak, Philipp Erfurth, Josep Espasa Reig, Giacomo Gabbuti, Janet Gornick, Demetrio Guzzardi, Elena Granaglia, Joe Hasell, Roberto Iacono, Rama Dasi Mariani, Branko Milanovic, Teresa Munzi, Jorg Neugschwender, Brian Nolan, Juan Palomino, Piotr Paradowski, Alberto Pozzolo, Antonio Scialà, and Philippe Van Kerm.

Regarding the Wealth Topography database, I acknowledge the instrumental initial contribution by Gonçalo Costa in conceptualizing the database and initiating the first systematic data-gathering effort. Giacomo Rella then oversaw the development of the Wealth Topography database under its current form. Max Longmuir followed in taking the lead. Both carried out various essential tasks, including conceptualization, designing the current data architecture, the national accounting mapping, the automation of data gathering, and the design of the detailed metadata complementing the database. I would also like to thank Ana Rojas Silvero for providing valuable assistance in gathering and classifying raw sources on household balance sheets. My thanks also go to Marco Ranaldi, Yaoqi Lin, and Pranabes Probeshika Dutta for their support with the initial data gathering.

The initial collaborative work of Frincasco Di Biase and Ercio Muñoz, proved instrumental in gathering the available data series for the Wealth Inequality section. Franziska Disslbacher took an oversight role of the Wealth Inequality database in 2022 and part of 2023, making possible a first database automation process.

In 2023 Matteo Targa took over Franziska's role and identified methods to automatically detect problems within the data series. Furthermore, together with Ignacio and Franziska, Matteo enabled the estimation of wealth inequality trends series using cross-national survey databases. Finally, Matteo has also taken the lead in the management, update, expansion, and streamlining process of the inequality trends database. The development of methodological tables to supplement the inequality trends series was carried out by me, with meticulous assistance from Francesco Di Biase, Franziska Disslbacher, and Matteo Targa throughout the process, which was instrumental in deriving the final tables in their current form. I am also very grateful to Tony Shorrocks for sharing Credit Suisse data.

Adam Rego Johnson played a pivotal role in creating compilation standards and manuals, as well as providing invaluable work in editing, proofreading, and classifying the tables. He also played a fundamental role in systematizing and classifying references, including within the Digital Library of Research on Wealth Inequality and the Data Sources Library. The initial work conducted by Carolyn Fisher, Ian Haberman, Twisha Asher, and subsequent contributions by Franziska Disslbacher, were important in finalizing the conceptual structure of the methodological tables, as well as providing content for specific sources.

Regarding the Taxes on Wealth section, I would like to acknowledge the dedicated work of Twisha Asher, who collected and classified estate, inheritance, and gift (EIG) tax policy parameters and researched corporate reports, official statistics, tax legislation documents, and research papers. She also played a crucial role in supporting the conceptualization and documentation of the current structure of the Taxes on Wealth database. I would also like to acknowledge important contributions by Manuel Schechtl, who assumed the oversight role on the development of the Taxes on Wealth database from Dec 2022 through July 2024. Jointly with Twisha Asher and Ignacio Flores, Manuel Schechtl also helped clarify the code to assemble the database and streamline the data collection process. Twisha Asher, alongside with Manuel Schechtl, also supervised a number of excellent research assistants who worked on different aspects of the project: Mei Li, Nolan Lyons, Yue Pan, Alex Parton, Sarah Russo, Jack Shea, and Tsu Zhu. Francesca Subioli and Luca Giangregorio joined Manuel's work in supervising the development of the tax section in early and late 2023, respectively. Both

have identified bottlenecks in the coding structure, fully restructured the Taxes on Wealth database using a new and more effective architecture, and planned part of the development of future database expansion. Moreover, they supervised the excellent research assistance of Martino Kuntze, Ali Jehanzaib, and Ghulam Shabir who helped systematize the information contained in relevant sources and helped debug the data entry process for the Taxes on Wealth section. Ignacio Flores played a crucial role in overseeing the overall architecture of the data warehouse. His work allowed for the integration of various components, resulting in a cohesive and well-structured data warehouse.

Special thanks to Mark Sheppard who helped to create the GC Wealth Project logo, the thumbnails, and visual banners for the website in the months leading up to the launch of the website. The project also relied on the expertise of external consultants. Toni Johnson provided invaluable support as director of communication in the early phase of the project. We extend thanks to Marcelo Agudo for his editing work, and to Robert Breen for his assistance with Tableau. We would like to acknowledge Rodica Ceslov and Connie Colvin for their support as project managers during earlier, separate phases of the project. Finally, we are grateful to the Lovelytics team for their assistance in the initial design of the Tableau dashboard and for their contribution to the website development.

Section 1

The GC Wealth Project

The GC Wealth Project, a central project of the Graduate Center's Stone Center on Socio-Economic Inequality, is a multi-year effort aimed at expanding and consolidating access to the most up-to-date research and information on wealth, wealth inequalities, and wealth transfers and related tax policies across countries and over time.

The GC Wealth Project website — first launched in June 2023 — is organized around two main components: a data warehouse of gathered and novel data that can be visualized in a variety of ways through the interactive dashboard, and a Digital Library of Research on Wealth Inequality. Both are designed to provide researchers, policymakers, journalists, and others interested in wealth and wealth taxation with open, unlimited access to an array of high-quality information and resources.

All of the data, including the tailored visualizations that users can create using the interactive dashboard, can be exported.

1.1 The Data Warehouse

The data warehouse includes four databases, which correspond to the four sections of the dashboard:

1. Wealth Topography
2. Wealth Inequality
3. Taxes on Wealth
4. Inheritance Trends

To create and populate the sections of our data warehouse, we drew on a large array of data sources. The

sections were filled by assembling secondary sources, extracting policy data, and/or querying and working directly with primary microdatasets.

The sources are all listed in our Data Sources Library.

The data warehouse is also complemented with full metadata descriptive information. The metadata provide detailed information on sources of data, longer descriptions of variables and the concepts used, procedures of aggregation and estimation, bibliography links, and complementary information.

All data files, metadata, supplementary variables, and documentation are available in our GitHub repository.

1.2 The Four Main Sections of the Warehouse

1) The Wealth Topography section includes cross-country data that capture, at the aggregate level, the evolution of household portfolios of assets and debt. Assets are metaphorically represented as "mountains and hills", while debts are visualized as "seas" of debt. The data come from national accounts, household surveys, and a range of research projects and reports.

   These data offer a unique view of aggregate household balance sheets. Country-specific portfolios are shaped by, and reflect, national characteristics, including demographic trends, inflation and interest rate dynamics, features of financial and credit markets, the relative importance of stock exchanges versus banking systems, the strength of asset management industries, and the preferential tax treatment of assets, as well as the preferences of households and the generosity of pensions systems.

2) The Wealth Inequality section presents a large comprehensive compilation of cross-national time-series data on wealth inequality. This section contains wealth inequality indicators (such as top shares and Gini coefficients) for many countries, as estimated in the existing literature and as derived from existing micro data sources. These data are accompanied by Methodological Tables that provide systematic assessments of the underlying concepts, methods, and sources for the estimation of wealth inequality trends.

   This section provides access to, and detailed information about, wealth inequality across countries and over time. To date, there is no comprehensive database that offers "off the shelf" indicators on wealth inequality levels and trends for a variety of different sources. Estimates of wealth distributions are much less settled than those of income distributions, and there is substantial controversy about how wealth inequality has evolved in recent years. A core value-added of

this section is that users have access to detailed information about the values provided and methodological information that will help them to navigate the inevitable complexity. Users can also exploit our classification of data types, source types, and unit of analysis to guide the choice of the most suitable indicator for their purpose.

3) The Taxes on Wealth section contains a comprehensive database on the evolution of estate, inheritance, and gift (EIG) taxation, both across countries and (forthcoming) across the U.S. states. This section focuses on the taxation of wealth transfers, that is, transfers from one household or individual to another, either when the donor is living (inter vivos gifts) or at the time of the donor's death (bequests). When assessing taxes, we distinguish among three types of taxes: those levied on estates (on the total amount bequeathed), on inheritances (on amounts received by individual recipients), and on gifts (given by living donors). The Taxes on Wealth section contains information on statutory tax schedules, marginal tax rates, top marginal rates, exemption thresholds, and tax revenues. Information on effective taxation is also derived and presented.

   Understanding how governments tax these transfers is essential because bequests, inheritances, and inter vivos gifts are crucial economic resources for households and because their scale has increased substantially in recent decades relative to total national income. Very little work has been done to analyze how patterns of wealth transfer taxation affect the extent of these transfers across countries and across households within countries. This systematic compilation of tax data will provide researchers a crucial tool for scholarship and policy analysis focused on the behavioral effects of wealth taxes.

4) The Inheritance Trends section, forthcoming later in 2023, will present cross-country estimates of annual flows of wealth left at death as well as gifts from living donors. The included estimates will be taken from existing works in the literature or derived using a variety of approaches drawing on national accounts data and survey data, as well as estate, inheritance, and gifts tax records.

1.3 The Digital Library of Research on Wealth Inequality

The Digital Library of Research on Wealth Inequality is a large, comprehensive, searchable database that includes abstracts and (when possible) full texts of important, innovative, and high-quality articles, chapters, and books focused on wealth inequality. The library is updated regularly and categorizes the included literature into eight subsections. Complete reference information is available in the BibTeX format, as are abstracts and (when possible) full texts.

1.4 How to Cite Our Data Source

If you are using the GC Wealth Project data in a report, monograph, paper, book, book chapter, journal article, dissertation, etc., include the citation in your bibliography as follows:

Morelli, Salvatore, Twisha Asher, Frincasco Di Biase, Franziska Disslbacher, Ignacio Flores, Luca Giangregorio, Adam Rego Johnson, Max Longmuir, Giacomo Rella, Manuel Schechtl, Francesca Subioli, and Matteo Targa, GC Wealth Project Data v.1.2, [year], accessed via http://wealthproject.gc.cuny.edu, on [date].

1.5 The Stone Center on Socio-Economic Inequality

The GC Wealth Project is a component of the James M. and Cathleen D. Stone Center on Socio-Economic Inequality, a research center housed at the Graduate Center of the City University of New York (CUNY).

The Stone Center conducts and promotes quantitative research using inequality as a lens on society, the economy, and politics. The faculty, postdoctoral scholars, and students working within the Stone Center share a commitment to scholarship that is data-driven, interdisciplinary, oriented toward policy and institutional change, and that addresses questions about inequality throughout the world.

The Stone Center's core functions include:

- Researching the causes, nature, and consequences of socio-economic inequality, with a specific mandate to expand research and research capacity related to wealth inequality;
- Training and teaching emerging inequality scholars at The Graduate Center/CUNY across a number of academic disciplines;
- Participating in discussions and debates on inequality through public programs and collaboration with journalists;
- Engaging in special programs and projects, such as the Inequality by the Numbers workshop, the Lee Rainwater Lecture Series, the Stone Center Working Paper Series, and an ever-expanding compilation of research spotlights (briefs), scholar interviews, and blog postings;
- Housing the U.S. Office of LIS, the renowned cross-national data center based in Luxembourg.

The Stone Center was created in 2016 with a generous gift from the James M. and Cathleen D. Stone Foundation.

Section 2

General Warehouse Structure

This section provides a comprehensive overview of the general structure of the data warehouse of the GC Wealth Project.

The data warehouse is organized in long format with a total of nine columns.

First of all, important information codifying the nature of the variable listed in the warehouse is stored in the column named *varcode*, and this is detailed in its own subsection below. Two additional columns store values related to each *varcode*. On the one hand, the column *value* stores numerical values like amounts in nominal currency, indices, shares, or rates. On the other hand.

There are five additional columns providing geographical and temporal information, population of reference, and sources (*GEO, GEO_long, year, percentile, source*). The *GEO* column refers to 2-character ISO codes for countries, while the *GEO_long* column refers to their full name. The *year* column is an integer variable, while the *percentile* column defines the population to which each observation corresponds. This is a string variable that takes values such as "p0p100" when observations refer to the whole population, as mostly happens with the Wealth Topography dashboard. Other percentiles, as appear in the Wealth Inequality section, can be defined using values between 0 and 100. For instance, the top 0.1% share of the population would be referred to as "p99.9p100". The source column contains information about the identifier of the specific source of the data.

Table 2.1: Warehouse Columns

GEO	GEO_long	year	percentile	varcode	value	source	longname	note	last_update

Finally, the variable *longname* is a string variable providing a description in plain language of each observation. This is defined automatically by an algorithm that draws all labels from our codebook/dictionary file (named dictionary.xlsx), available in our GitHub repository.

Importantly, the data warehouse is also available in a more detailed version, which contains a long list of descriptive metadata information. The complete warehouse is *warehouse_meta*. Metadata include information such as comments on the methodology used to compile the data, and any limitations or caveats associated with the data, as well as detailed information about the definition of our variables, units of analysis, and full spelling of the sources of data, including links to full curated bibliographic citation details. The metadata version is essential for researchers and analysts who require a deeper understanding of the underlying data and its quality. It is available for download alongside the warehouse and can also be accessed through our website and repository.

2.1 The varcode

The *varcode* column allows users to identify the variable and concept at hand. It is also designed to indicate information about the specific warehouse section and sector, as well as section-specific information. Each *varcode* variable has a pre-determined structure, and consists of five main components: Section, Sector, Variable Type, Concept, and Section-Specific info.

$$\underbrace{A}_{Section} - \underbrace{BB}_{Sector} - \underbrace{CCC}_{VariableType} - \underbrace{DDDDD}_{Concept} - \underbrace{ZZ}_{Section-Specific}$$

The first 1-digit component, Section, defines the broad section in which the variable belongs, such as the Wealth Inequality or the Wealth Topography section.

The 2-digit Sector component provides additional granularity, such as the specific institutional sector being measured, e.g., the Household sector including the Non-Profit Institutions Serving Households.

The 3-digit Variable Type component denotes the type of variable being measured, e.g., the Gini coefficient, Top or Bottom shares, a tax threshold or aggregate wealth.

The 6-digit Concept component provides more detailed information about the variable being measured, such as the specific metric being used, while the 2-digit Section-Specific component can be used to further characterize the variable within a particular section of the warehouse (e.g., in the context of the Taxes on Wealth section, each variable will be associated to a particular tax bracket if necessary).

Table 2.2: Section codes

code	label
x	Taxes on Wealth
t	Wealth Inequality
p	Wealth Topography

2.2 Supplementary Variables

To facilitate broader use and comparability of the general warehouse data, a set of additional supplementary variables covering various is provided to complement the data warehouse. These additional variables are available on our GitHub repository and stored in a downloadable file named "supplementary_var". This file contains all the supplementary information, and it is structured in a wide format, i.e., all additional variables are displayed in columns, with each row uniquely identified by geographical classification and year (i.e. *GEO* and *year*). Therefore, these supplementary variables can easily be merged with the warehouse data using *GEO* and *year* as identifiers. Currently, the supplementary variables are included from a list of external data sources, such as the World Inequality Database, World Bank, Comparative Political Data Set and Parliaments and Government Database.

The supplementary variables downloaded from the World Inequality Database – downloaded on July 16th, 2024 – allows users to carry out various transformations of the data. In particular, data can be used to implement inflation adjustments, currency conversion rates, or to include population estimates (such as per capita or per adult), and macroeconomic values (such variables as % of GDP or % of National Income), and are intended to enhance users' capacity for insightful comparisons and analysis.

To improve comparability with other institutional data, we provide the official country denomination adopted by the World Bank, along with their income groups classification updated as of July 1, 2024 [93] and available since 1987 - low, lower-middle, upper-middle, high income. We also include the regional classification: East Asia & Pacific, Europe & Central Asia, Latin America & Caribbean, Middle East & North Africa, North America, South Asia, Sub-Saharan Africa. For additional details about the income group classification, please visit the "Knowledge Base" page of the World Bank.

Lastly, to foster interdisciplinary use of our data and stimulate research across the entire spectrum of social sciences, we introduce a new variable that captures the political orientation of the government in charge each year. This variable categorizes governments based on their political orientation (hegemony of right-wing, dominance of right-wing, balance between left and right parties, dominance of left, hegemony of left), by combining two primary sources concerning the political spectrum and election results [11, 34], both widely

used in the European Journal of Political Research.

The definition of the political orientation adopted in these two main sources is based on the government composition. Following Armingeon et al. [11] (Comparative Political Data Set, 1960-2022), the cabinet composition takes different values depending on the ratio of the party seats in parliament over the total parliamentary seats of all governing parties. For example, there will be a "dominance of social-democratic and other left parties" if the seat share of all social-democratic and left governing parties exceeds 66.67% of the total parliamentary seats of all governing parties. Conversely, there is a "hegemony of right-wing (and centre) parties" when no left-wing parties participate in the cabinet. The definitions of left and right in Armingeon et al. [11] and Döring and Manow [34] (ParlGov Database) follow the political science literature and are detailed in their specific documentation. Due to distinctive nature of the United States political spectrum and history, its political cycle is typically identified using "Democrat" and "Republican".

Combining both sources we are able to cover 38 countries over almost the whole XX century, with the exception of the eastern-Europe countries entering the sample after the 1989.

Table A.1 in Appendix A below provides a summary of the supplementary variables employed in the project. For more comprehensive information on the construction of these variables, please consult their original documentation.

Section 3

Wealth Topography Section

3.1 Introduction to the Wealth Topography Section

The Wealth Topography section includes cross-country data that capture, at the aggregate level, the evolution of household portfolios of assets and debt. The data come from national accounts, household surveys, and a range of research projects and reports.

These data offer a unique view of aggregate household balance sheets. Country-specific portfolios are shaped by, and reflect, national characteristics, including demographic trends, inflation and interest rate dynamics, features of financial and credit markets, the relative importance of stock exchanges versus banking systems, the strength of asset management industries, and the preferential tax treatment of assets, as well as the preferences of households and the generosity of pensions systems.

This chapter introduces the categories of the Wealth Topography database and the construction of each concept. We refer the interested reader to the Technical Documentation of the Wealth Topography for all information related to the treatment of each source of data as well as the country-specific data coverage.

3.2 The `varcode` in the Wealth Topography Section

As described in the general warehouse structure section, for each country-source pair, the `varcode` is a string that identifies a unique time-series by means of five elements. The first element of the `varcode` is a 1-digit code that identifies the Section of the GC Wealth Project, which for the case of Wealth Topography takes the value `p`. Hence, `varcode` takes the following form:

$$\underbrace{p}_{\text{Section}} - \underbrace{BB}_{\text{Sector}} - \underbrace{CCC}_{\text{Variable Type}} - \underbrace{DDDDDD}_{\text{Concept}} - \underbrace{ZZ}_{\text{Section Specific}}$$

3.2.1 `Sector`

The second element of the `varcode` identifies the sector to which the time-series refers. The Wealth Topography database reports aggregate wealth and the composition of assets and liabilities of three institutional sectors: Households, NPISH (non-profit institutions serving households), and Households & NPISH sectors.[1] The classification of institutional sectors used in the Wealth Topography database (and in the GC Wealth Project more in in general) mirrors the classification used by the System of National Accounts 2008 (SNA2008, hereafter) and its European counterpart, the European System of Accounts 2010 (ESA2010. hereafter). The institutional sectors are reported in Table 3.1, where the column "Code" reports the sector identifier used in the `varcode` while the column "Description" reports a detailed, non-technical, description of each sector.

Table 3.1: Wealth Topography: Sector

Code	Sector	Description
hs	Households	The household sector gathers together all individuals or group of individuals who live together, who pool their income and wealth, and make joint economic decisions (e.g., consumption). The household sector is one of the institutional sectors constituting the national economy.
hn	Households & NPISH	The households and NPISH sector (non-profit institutions serving households) gathers together households (all individuals or group of individuals who live together, who pool their income and wealth, and make joint economic decisions) and non-profit organizations that primarily provide services to households (such as charities, religious institutions, and social clubs). The household and NPISH sector is one of the institutional sectors constituting the national economy.
np	NPISH	The NPISH (non-profit institutions serving households) sector gathers together non-profit organizations that primarily provide services to households. This includes organizations such as charities, religious institutions, and social clubs. The NPISH sector is one of the institutional sectors constituting the national economy.

[1] Other institutional sectors (non-financial corporations sector, financial corporations sector, general government sector, and the rest of the world) are not currently included in the database.

3.2.2 `Variable Type`: Consolidation

The third element of the `varcode` identifies the `Variable Type` which, in the Wealth Topography database, coincides with the consolidation status. The Wealth Topography reports outstanding levels of assets and liabilities and net wealth for the institutional sectors considered. In the SNA2008, outstanding levels or stocks for a given sector are obtained by aggregating the accounts of the units of the sector, and the aggregation process can differ according to the treatment of transactions within the sector. Within-sector transactions can be consolidated or non-consolidated accounts. Consolidation refers to the practice of eliminating any transaction between units or sub-sectors within the same sector. In this case, any remaining transaction is a transaction with other institutional sectors of the economy. For example, in a consolidated financial account, a loan between two households within the household sector would be eliminated, and the remaining loans would reflect transactions with other sectors of the economy (e.g., the rest of the world, the government sector, the non-financial corporations sector, or the financial corporations sector). In contrast, in a non-consolidated account, such an elimination is not carried out and the aggregation across units within the same sector includes all types of transactions, regardless of the counterpart. In this case, a loan between two households within the households sector would be counted as both an asset and a liability. In practice, most statistical agencies publish only non-consolidated accounts because the construction of consolidated accounts requires knowing the sender and the recipient of all transactions.

Table 3.2 reports under the column "Code" the consolidation status identifier used in the `varcode` of the Wealth Topography database while the column "Description" reports a detailed, non-technical description. If a source in the Wealth Topography database does not provide any information about the consolidation status, we classify them simply as "Aggregate".

Table 3.2: Wealth Topography: Variable Type

Code	Consolidation status	Description
agc	Aggregate (Consolidated)	Aggregate value for a given institutional sector for which transactions that occur between units within the same sector are eliminated.
agn	Aggregate (Non-consolidated)	Aggregate value for a given institutional sector for which transactions that occur between units within the same sector are not eliminated. This may result in double-counting of assets and liabilities
agg	Aggregate	Aggregate value for a given institutional sector. The value is reported without knowing whether transactions that occur between units within the same sector are eliminated or kept during the aggregation.

3.2.3 `Concept`

The fourth element of the `varcode` identifies the `Concept`. In the Wealth Topography database, a concept is a macro-category of the balance sheet, computed by aggregating different asset and liability classes. The construction of such concepts and the aggregation procedure are explained in Section 3.3. The concepts and the corresponding identifiers used in the `varcode` of the Wealth Topography database, together with a detailed description, are reported in Table 3.3.

Table 3.3: Wealth Topography: Concept

Code	Concept	Description
netwea	Net Wealth	Net wealth is the sum of all tangible assets (real estate properties and land, valuables, plants, machineries, equipment, etc.) and intangible assets (stocks, bonds, balances of current, saving, and investment accounts, private pension and life insurance funds, etc.) minus the sum of all debts and liabilities (mortgages, loans, and credit card debt).
nnhass	Financial Assets & Fixed Capital of Personal Businesses	Sum of all financial assets (such as stocks, shares or equities in corporations and quasi-corporations, corporate and government bonds, mutual funds, cash, current, savings and investment accounts, time deposits or certificates of deposit (CDs), accumulated balance in private pension funds, cash or reserve value of life insurance funds, etc.) and the fixed capital stock of small personal businesses of producer households (such as plants, machinery, equipment, inventories, software, and goodwill).
fliabi	Debt	Debts, or liabilities, are financial obligations that generally result from borrowing. For households, the most common form of debt is the mortgage, a loan taken out by an individual or a household to purchase a home or other real estate properties. Other forms of debt include credit card debts, auto loans, and student loans.
fliabm	Debt secured by a mortgage	Debt secured by a mortgage are loans taken out by an individual or a household to purchase a home or other real estate properties.
facdbl	Cash, Deposits, Bonds & Loans	Cash can be held in the form of banknotes, coins, or digital currency. Bonds represent a loan made by households to a corporation or government entity and provide a fixed return to the investor in the form of interest payments. Deposits include both current accounts (available on demand) and savings accounts (generally interest-bearing instruments with limited withdrawal). Loans are the money lent to individuals or households for which they owe the principal and interest to the creditors.
fadepo	Deposits	Deposits include both current accounts (available on demand) and savings accounts (generally interest-bearing instruments with limited withdrawal).

faeqfd	Stocks, Business Equities & Fund Shares	Stocks (or shares) and business equities are securities representing the ownership in a corporation or quasi-corporation and entitling the holder to a portion of the company's profits. Fund shares represent the participation in mutual or investment funds which are investment vehicles that pool together money from multiple investors to purchase a portfolio of securities such as stocks, bonds, or other assets.
falipe	Pensions & Life Insurance	Private pension assets refer to funds that are set aside by an individual (or an employer) to provide income during retirement (excluding public pension and social security schemes). Pension assets can take the form of defined benefit plans (retirement income benefits are fixed) or defined contribution plans (retirement income benefits are dependent on contributions). Life insurance assets refer to the cash value or reserve value of a life insurance policy (where the policyholder pays premiums in exchange for a death benefit that is paid out to their beneficiaries upon their death).
nfabus	Fixed Capital of Personal Businesses	Fixed capital of small personal businesses represents the non-financial assets that are used by a small personal business to produce goods or services and to support the ongoing operations of the business. This category includes both tangible assets (such as plants, machineries, equipment, inventories, valuables) and intangible assets (such as software and goodwill).
nfahou	Housing & Land	Housing identifies the value of residential buildings or structures that are owned by households (may include single-family homes, apartments, condominiums, and other types of housing). Land assets include agricultural land, residential land, commercial land, and industrial land. This includes land underlying dwellings, and other buildings and structures.
nfhous	Housing	Housing identifies the value of residential buildings or structures that are owned by households (may include single-family homes, apartments, condominiums, and other types of housing).
nfalan	Land	Land assets include agricultural land, residential land, commercial land, and industrial land. This includes land underlying dwellings, and other buildings and structures.
offsho	Total Financial Offhore Wealth	Offshore financial wealth refers to the equities, bonds, mutual fund shares, and associated bank deposits owned by households in banks outside of their country of residency.
nfadur	Consumer Durable Goods	A durable good is a consumption good that can deliver useful services to a consumer through repeated use over an extended period of time

We use a stylized balance sheet to show the relationship between the concepts in Table 3.3. The balance sheet is organized into two panels: Assets, and Liabilities and Net Wealth. We also report illustrative values for each

concept. Among assets, "Housing & Land" and "Financial Assets & Fixed Capital of Personal Businesses" are the two main concepts. "Housing & Land" is the sum of the concepts "Housing" and "Land". The concept "Financial Assets & Fixed Capital of Personal Businesses", in turn, equals the sum of the following concepts: "Fixed Capital of Personal Businesses", "Cash, Deposits, Bonds & Loans", "Stocks, Business Equities & Fund Shares", and "Pensions & Life Insurance". "Deposits" is a part of "Cash, Deposits, Bonds & Loans", but also a concept on its own. We also include additional concepts "Offshore Financial Wealth" and "Consumer Durable Goods". The concept "Debt" constitutes the liability side of the balance sheet. As mortgage debt is the key component of debt in many countries, the concept "Debt Secured by a Mortgage" provides data on debt at an additional level of disaggregation. Finally, the concept "Net Wealth" is the balancing item and it equals the difference between total assets ("Housing & Land" and "Financial Assets & Fixed Capital of Personal Businesses") and "Debt". Note that we follow the standard definition of net wealth and, therefore, do not include offshore financial wealth or consumer durable goods in the net wealth definition. That is why we separate the two concepts in the right panel of the balance sheet.

Table 3.4: Wealth Topography: Balance Sheet Example

Assets		Liabilities and Net Worth	
Housing & Land	1510		
Housing	800		
Land	710		
Financial Assets & Fixed Capital of Personal Business	3518		
Fixed Capital of Personal Businesses	26		
Cash, Deposits, Bonds & Loans	684		
Deposits	350		
Stocks, Business Equities & Fund Shares	1550		
Pensions & Life Insurance	1258		
Offshore Financial Wealth	241		
Consumer Durables	278		
		Debt	695
		Debt Secured by a Mortgage	400
		Net Wealth	4333
		Net Wealth incl. Offshore Wealth and Consumer Durable Goods	4852

3.2.4 `Section-Specific`: Recording of Financial Position

The fifth element of the `varcode` is a `Section-Specific` string which, in the Wealth Topography databse, corresponds to the financial position of each concepts. Financial assets may be recorded gross or net of all liabilities, at a given point in time. Similarly, debt securities can appear both as assets or as liabilities. To distinguish between the financial position of each concept, the Wealth Topography distinguishes between three types of financial position: gross assets (`ga`), net assets (`na`), and liabilities (`lb`). When this classification is not possible, the financial position is not applicable (`_`). Table 3.5 provides a taxonomy of financial positions together with a non-technical description for each.

Table 3.5: Wealth Topography: Section-Specific

Code	Financial position	Description
ga	Gross Assets	Gross assets are the total value of all assets before subtracting the value of debts and liabilities.
na	Net Assets	Net assets are the total value of all assets after subtracting the value of debts and liabilities.
lb	Liabilities	Liabilities are financial obligations or debts that an individual, company, or organization owes to another party.
___	Not Applicable	Not Applicable

3.3 Construction of the Wealth Topography Database

We now give a brief and stylized description of the process underlying the construction of the Wealth Topography database. In its most stylized version, this process involves three steps (synthesized in the flow chart):

1. Identify and download raw data for each source.
2. Map every raw source into national accounting concepts using the Wealth Topography Conceptual Grid.
3. Create Wealth Topography macro-category ('concept') by aggregating the variables from each source (transformed following step 2) using the Wealth Topography Composition Rules.

We now provide a detailed explanation of all steps put in place to construct the Wealth Topography database.

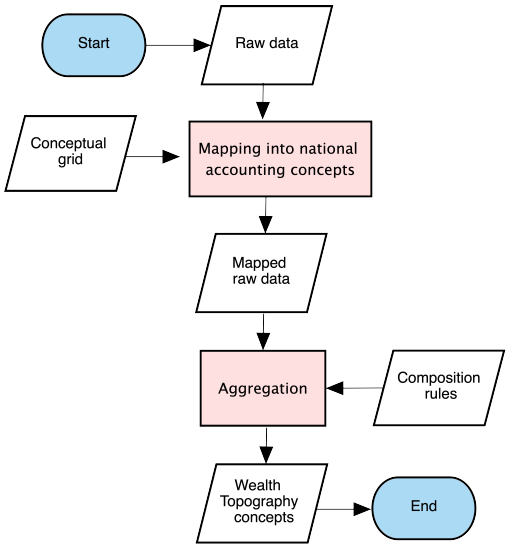

Figure 3.1: Wealth Topography: Flow Chart

3.3.1 Identify and Download Raw Data for Each Source

The starting point is the identification of raw data on balance sheets from various sources, such as national accounts, household surveys, and a range of research projects and reports. Once the sources have been identified and the raw data downloaded, we classify them in three macro groups:

1. Raw data sources published by central banks and national statistical institutes that use the SNA2008/ESA2010 framework to organize and disseminate the data. We refer to these raw data sources simply as cross-national official statistics.

2. Raw data sources published by central banks and national statistical institutes that use variants of the SNA2008/ESA2010 framework or other frameworks to organize and disseminate the data. We refer to these raw data sources as cross-national official statistics that use variants of SNA2008/ESA2010 framework.

3. Raw data sources contained in surveys and academic papers or published by central banks and research institutes that use frameworks different from the SNA2008/ESA2010 framework to organize and disseminate the data. We refer to these data sources as cross-national official survey data or cross-national academic research that do not use the SNA2008/ESA2010 framework.

3.3.2 Map Raw Data into National Accounting Concepts

Once raw data have been obtained and classified, we harmonize them using the Wealth Topography Conceptual Grid. This grid, inspired by National Accounts, assigns an alphanumeric identifier to each item or

instrument of the balance sheet.[2] An extract of the grid can be seen in Table 3.6. Under the column "Code", we report the code that identifies each item of the balance sheet (e.g., AN111 stands for Dwellings). The code consists of two elements (letters and numbers) and a special character for the case of financial assets and liabilities. The alphabetic part of the code identifies whether a specific balance sheet component falls in the category of non-financial assets (AN), financial assets (A_AF), or liabilities (L_AF), while numbers identify the class of assets and liabilities to which the instrument belongs.

Equipped with the grid, we can map each raw source into national accounting concepts with the aim of obtaining harmonized data on net wealth, assets, and liabilities that can be compared across countries and sources. According to the type of raw data source, we distinguish between two types of mapping:

- Automatic mapping (for cross-national official statistics). For raw data sources published by central banks and national statistical institutes that use the SNA2008/ESA2010 framework to organize and disseminate the data, the mapping of raw data into national accounting concepts is straightforward.
- Conceptual or manual mapping (for cross-national official statistics that use variants of SNA2008/ESA2010 framework). For raw data sources published by central banks and national statistical institutes that use variants of the SNA2008/ESA2010 framework or other frameworks to organize and disseminate the data, the mapping of raw data into national accounting concepts is not straightforward. Therefore, we manually map each series from the raw data source to elements of the grid. The mapping is conceptual and based on our reading of source-specific documentation. All source-specific manual mapping tables are reported in Appendix B.4.

For cross-national official survey data or cross-national academic research that do not use the SNA2008/ESA2010 framework, we build source-specific grids to help cross-walking from raw data to the national accounting concepts in Table 3.6. For completeness, we report the source-specific grids together with source-specific documentation in Appendix B.4. We followed the SNA2008/ESA2010 definition for consumer durable goods and debt secured by a mortgage. For offshore financial wealth, we created a framework which is analogous to the financial wealth definition.

Table 3.6: Wealth Topography: Conceptual Grid

Code	Description	Financial position
AN	Produced and non-produced non-financial assets	ga
AN1	Produced non-financial assets	ga

[2]For the original table used in ESA2010 @ESA2010, see Section 'IV.3: Balance sheets: Closing balance sheet' in 'Table 24.6 — Full sequence of accounts for households' of the European System of National Accounts accessed via https://ec.europa.eu/eurostat/esa2010/.

AN11	Fixed assets by type of assets	ga
AN111	Dwellings	ga
…	…	…
…	…	…
A_AF	Financial assets	ga
A_AF1	Monetary gold and SDRs	ga
A_AF11	Monetary gold	ga
A_AF12	SDRs	ga
A_AF2	Currency and deposits	ga
A_AF21	Currency	ga
…	…	…
L_AF	Liabilities	lb
…	…	…
L_AF3	Debt securities	lb
L_AF31	Short-term debt securities	lb
L_AF32	Long-term debt securities	lb
L_AF4	Loans	lb
L_AF41	Short-term loans	lb
L_AF42	Long-term loans	lb
…	…	…
A_AXF	Financial assets held offshore	ga
XDHHCE	Consumer durables	ga

3.3.3 Create Wealth Topography Concepts Using Our Composition Rules

For raw sources classified as cross-national official statistics (independently of whether the SNA2008/ESA2010 framework is used), the mapping yields harmonized series on net wealth, assets, and liabilities. The next step is to aggregate these harmonized raw data into the macro-categories (`concept`) of the Wealth Topography database. Aggregation is carried out through the general composition rules in Table 3.7.

In practice, we use an extended set of composition rules relative to those displayed in Table 3.7, since different data sources provide different levels of aggregation for the sub-components of the balance sheet. For example, the `concept` "Stocks, Business Equity & Fund Shares" can be computed by aggregating different variables. On the one hand, for some data sources, the `concept` "Stocks, Business Equity & Fund Shares" is set equal to "Equity and investment fund shares (A_AF5)". On the other hand, when the aggregate variable is missing, we obtain "Stocks, Business Equity & Fund Shares" by summing up "Equity (A_AF51)" and "Investment

fund shares/units (A_AF52)". We always provide a detailed account of which composition rule has been used to construct a data point in the Wealth Topography database in the metadata section of the warehouse file or graphs available to users through the website of the GC Wealth Project. All source-specific composition rules used in the Wealth Topography database are reported in the source-specific documentation.

Finally, for raw data sources classified as cross-national official survey data or cross-national academic research that do not use the SNA2008/ESA2010 framework, we consider ad-hoc source-specific composition rules. In this case, raw data sources are not harmonized by mapping them into national accounting concepts using the grid. Rather, based on our reading of source-specific documentations, the aggregation of this raw data type uses macro-categories that are coherent and comparable to those obtained from cross-national official statistics. We provide a detailed treatment of these sources in Appendix B.4.

3.4 Additional Information on the Wealth Topography Section

For any additional information about the Wealth Topography database the reader can refer to Appendix B which includes a list of all sources covered by the Wealth Topography database, an extensive treatment of the composition rules, and detailed source-specific documentations.

Table 3.7: Wealth Topography: General Composition Rule

Code	Concept	Composition rule using codes	Composition rule
netwea	Net Wealth	(AN1) + (AN2) + (A_AF) - (L_AF)	(Produced non-financial assets) + (Non-produced non-financial assets) + (Financial assets) - (Liabilities)
nnhass	Financial Assets & Fixed Capital of Personal Businesses	(AN1) + (AN2) + (A_AF) - (AN111) - (AN112) - (AN211)	(Produced non-financial assets) + (Non-produced non-financial assets) + (Financial assets) - (Dwellings) - (Other buildings and structures) - (Land)
fliabi	Debt	(L_AF3) + (L_AF4) + (L_AF5) + (L_AF6)	(Debt securities, liab.) + (Loans, liab.) + (Equity and investment fund shares, liab.) + (Insurance, pension and standardized guarantee schemes, liab.)
fliabm	Debt secured by a mortgage	(XAF42LM)	(Long-term loans secured by a mortgage, liab.)
facdbl	Cash, Deposits, Bonds & Loans	(A_AF2) + (A_AF3) + (A_AF4)	(Currency and deposits) + (Debt securities) + (Loans)
fadepo	Deposits	(A_AF22) + (A_AF29)	(Transferrable deposits) + (Other deposits)
faeqfd	Stocks, Business Equities & Fund Shares	(A_AF5)	(Equity and investment fund shares)
falipe	Pensions & Life Insurance	(A_AF6)	(Insurance, pension and standardized guarantee schemes)
nfabus	Fixed Capital of Personal Businesses	(AN1) + (AN2) - (AN111) - (AN112) - (AN211)	(Produced non-financial assets) + (Non-produced non-financial assets) - (Dwellings) - (Other buildings and structures) - (Land)
nfahou	Housing & Land	(AN111) + (AN112) - (AN1123) + (AN21111)	(Dwellings) + (Other buildings and structures) + (Land)
nfalan	Land	(AN211)	(Land underlying dwellings) + (Land underlying other buildings and structures) + (Land under cultivation)
nfhous	Housing	(AN111) + (AN112)	(Dwellings) + (Other buildings and structures)
offsho	Offshore Financial Wealth	(A_AXF)	(Financial assets held offshore)
nfadur	Consumer Durable Goods	(XDHHCE)	(Consumer durables)

Section 4

Wealth Inequality

4.1 Introduction to the Wealth Inequality Section

The Wealth Inequality section presents a large comprehensive compilation of cross-national time-series data on wealth inequality. This section contains wealth inequality indicators (such as top shares and Gini coefficients) for many countries, as estimated in the existing literature and as derived from existing micro data sources. These data are accompanied by Methodological Tables that provide systematic assessments of the underlying concepts, methods, and sources for the estimation of wealth inequality trends. This section provides access to, and detailed information about, wealth inequality across countries and over time. To date, there is no comprehensive database that offers off the shelf indicators on wealth inequality levels and trends for a variety of different sources. Estimates of wealth distributions are much less settled than those of income distributions, and there is substantial controversy about how wealth inequality has evolved in recent years. A core value-added of this section is that users have access to detailed information about the values provided and methodological information that will help them to navigate the inevitable complexity. Users can also exploit our classification of data types, source types, and units of analysis to guide the choice of the most suitable indicator for their purpose.

4.2 The Structure of the Wealth Inequality Section

In the Wealth Inequality database, each estimate of wealth inequality (`value`) is uniquely identified by the combination of the reference country indexed by a two-digit identifier (`GEO`) and the country name (`GEO_long`), the reference year (`year`), the data source (`source`), the `varcode`, and a `percentile`.

Table 4.1: Introducing the GC Wealth Inequality Database - Snippet

source	GEO	GEO_long	year	varcode	percentile	value
HFCS_ineq	AT	Austria	2010	t-hs-dsh-netwea-ho	p0p10	-0.7607081

HFCS_ineq	AT	Austria	2010	t-hs-dsh-netwea-ho	p95p99	24.6391010
HFCS_ineq	AT	Austria	2010	t-hs-dsh-netwea-ho	p99p100	22.9756908

Table 4.1 provides a small extract from the Wealth Inequality database. This table displays data sourced from the HFCS for Austria in the year 2010. The series reported in the `value` column correspond to an inequality indicator (`varcode`) calculated across various percentiles (`percentile`). Specifically, the `varcode` column provides details about the unit of analysis and the type of wealth inequality measure, while the `percentile` column indicates which segment of the distribution the estimate pertains to. The subsequent sections elaborate on the variables `varcode` and `percentile`

4.3 The `varcode` in the Wealth Inequality Section

In the Wealth Inequality section, two of the five elements of `varcode` are fixed across the entire database. The constant elements are the first, that identifies the Section of the GC Wealth Project and takes the value `t`, , and the second, that indexes the household sector and takes the value `hs`. The `Variable Type`, the `Concept`, and the `Section-Specific` parts of the `varcode` vary within a source and across sources and are explained in detail in what follows. Hence, `varcode` takes the following form:

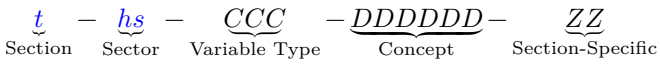

t
Section
hs
Sector
CCC
Variable Type
DDDDDD
Concept
ZZ
Section-Specific

Table 4.2: Wealth Inequality: Variable Type

Code	Label	Description
dsh	Share of Total Net Wealth	The share of a given asset (or assets group) on total net wealth. For instance, we may refer to the overall net wealth (or any given asset, i.e. housing, financial assets, debt) that individuals, household, or group owns as a share of total net wealth. For example, if the total net wealth of a country is €10,000 billion and a group's net wealth is €2,000 billion, their share of total net wealth would be 20%. Moreover, if half of this group's wealth is held in housing wealth, their distributional share of housing would be 10%.
owr	Ownership Rate	The proportion of households or individuals who self-report owning a specific asset or good. Calculated as the number of households (or individuals) reporting ownership divided by the total number of households (or individuals) in the reference population.
gin	Gini Coefficient	The Gini coefficient is a statistic that summarizes the overall distribution of income or wealth that is commonly published by statistical agencies. The coefficient ranges from 0 (perfect equality) to 100 (maximum inequality). A Gini coefficient of G per cent means that, if we take any 2 households from the population at random, the expected difference is 2G per cent of the mean. So that a rise in the Gini coefficient from 30 to 40 per cent implies that the expected difference (in wealth for instance) has gone up from 60 to 80 per cent of the average wealth.
avg	Average Wealth	Average wealth refers to the total value of assets (such as property, savings, investments, and other financial assets) owned by a group of individuals or households divided by the total number of individuals or households in that group.
thr	Threshold	A threshold represents a minimum or maximum value that must be met or exceeded, for instance, the minimum value of net wealth that is needed for an individual to belong to the group of the richest 1% of adults, or the maximum value of net wealth that is needed for an individual to belong to the group of the poorest 50% of adults.
tot	Total	It represents the total value of a variable. For instance, total population, or total revenue raised from the inheritance tax.

4.3.1 `Variable Type`

The third element of the `varcode` identifies the broad type of inequality measure. Table 4.2 provides the permitted strings of the `Variable Type` within the `varcode` in the Inequality Trends database, together with a label and a description. Note that data on monetary units (averages, thresholds, and totals) are always shown in national currency, in nominal term with no adjustment to inflation. The supplementary variables (see Section 2.2) could be used to transform all monetary values into other currencies and to adjust for inflation dynamics.

4.3.2 `Concept`

The fourth element of the `varcode` identifies the `Concept`. In the Wealth Inequality database, a concept is the asset category the indicator refers to. The nomenclature and definitions are borrowed from the Wealth Topography Section and detailed in Table 4.3. The Table reports the concepts and the corresponding identifiers used in the `varcode` of the Wealth Inequality database, together with a detailed description and the list of available `Variable Type` associated with each concept. For example, with respect to total net wealth (`netwea`), the available indicators include averages (`avg`), shares (`dsh`), thresholds (`thr`), and totals (`tot`) held by different segments of the distribution (further specified by the variable `percentile`), as well as overall Gini (`gin`) estimates.

Table 4.3: Wealth Inequality: Concept Dictionary

Code	Label	Var Type
netwea	Net Wealth	dsh, thr, gin, avg, tot
nnhass	Financial Assets & Fixed Capital of Personal Businesses	avg, dsh, tot, owr
nfahou	Housing & Land	avg, dsh, tot, owr
fliabi	Debt	avg, dsh, tot, owr
fadepb	Bank accounts	owr
fadepo	Deposits	owr
faeqfd	Stocks, Business Equities & Fund Shares	owr
falipe	Pensions & Life Insurance	owr
nfaala	Agricultural Land	owr
nfabus	Fixed Capital of Personal Businesses	owr
nfadur	Durable Goods	avg, dsh, tot
nfhous	Housing	owr

Table 4.4: Wealth Inequality: Section-Specific

Code	Label	Description
ia	Individuals - Adults	Estimates of wealth inequality refer to the distribution across individual holders (depending on the source, at least 15, 16, 18, or 20 years old). In rare cases, this label also refers to individuals assumed to be holding the equivalized wealth of the household. The equivalence scale used in most cases is the "modified OECD scale,", which gives a weight of 1 to the first adult, of 0.5 to each additional adult, and of 0.3 to each child. This means that total wealth of a family of 2 adults and 2 children is divided by 2.1. In other rare cases, it refers to the distribution across all individuals, irrespective of their age.
es	Individuals - Adults (equal split)	Total wealth of the household is divided equally between the two adult partners. Adults are generally defined as individuals at least 18 or 20 years old. This category could also include cases in which total wealth of the household is divided equally among all members of the household.
tu	Tax Units	Data on wealth holding refer to a group of individuals who are subject to the same tax laws (tax unit). In most cases, a tax unit is composed of one or more people who file a tax return together, such as a married couple filing jointly or a family filing as dependents on a parent's tax return.
ho	Households	Data on wealth holding refer to a household, defined as a group of people who live together in the same dwelling unit. The members of a household may be related by blood, marriage, or adoption, or they may be unrelated individuals who have chosen to live together for other reasons.

4.3.3 `Section-Specific`

In the Wealth Inequality database, the section-specific part of the `varcode` refers to the unit of analysis of the wealth inequality indicator. The databases distinguishes four types of units of analysis: individual adults (`ia`), individual adults with equal split (`es`), tax units (`tu`), and households (`ho`). The list of permitted strings and a short description is provided in Table 4.4.

4.4 The `percentile` variable in the Wealth Inequality Section

In addition to the `varcode`, values are indexed by the `percentile` variable. This variable identifies the reference segment of the net wealth distribution for each inequality indicator. In particular it specifies the lower-bound and the upper-bound percentiles delimiting the reference group. For the share of wealth held by the richest 1%, for instance, the `percentile` variable corresponds to *p99p100*. If the index refers to the overall population, as in the case of the overall net wealth or the Gini index, the `percentile` variable corresponds to *p0p100*. We provide a selection of permitted percentiles in Table 4.5; the full list can be found in the `dictionary.xlsx`.

Table 4.5: Wealth Inequality: Selected Percentiles

Code	Label	Description
p0p10	Poorest 10%	Group representing the bottom decile (10%) of the wealth distribution, meaning that 90% of the population would have higher wealth levels in comparison.
p0p100	Overall Population	Everyone in the reference population
p90p99	Next 9% (90th-99th Percentiles)	Group with wealth level higher than the top decile but not high enough to enter the group of the richest 1 % in the population
p99.999p100	Richest 0.001%	Group representing the richest 0.001% of the wealth distribution
p99p100	Richest 1%	Group representing the top percentile (1%) of the wealth distribution, meaning that 99% of the population would have lower wealth levels in comparison.

4.5 Construction of the Wealth Inequality Section

The procedure used to construct the Wealth Inequality database is outlined in Figure 4.1. First, we identify the relevant sources and obtain the raw data. Second, we transform and harmonize the raw data to fit our standards in terms of format and structure. Third, we run a set of tests and append the source-specific

estimates to the database. Concurrently, we develop and write a detailed **Methodological Table**.

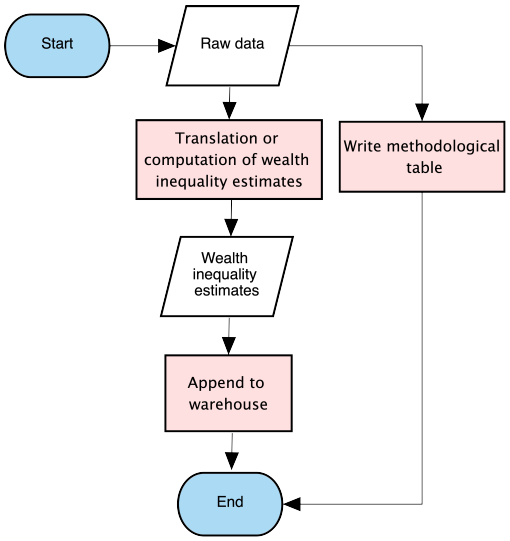

Figure 4.1: Wealth Inequality Workflow

4.5.1 Step 1: Identification and Classilfication of Sources

The starting point is the identification of relevant data on wealth inequality estimates. These estimates can originate from different *types* of sources, like academic, government, and corporate research, as well as cross-national research and official statistics. Table 4.6 provides an overview of the permitted types of source.

Table 4.6: Wealth Inequality: Source Types

Label	Description
Cross-national official statistics	Cross-national data from official institutions, such as national accounts from central banks.
Cross-national official survey data	Cross-national survey data from official institutions, such as household finance surveys from national statistical offices.
Cross-national corporate research	Cross-national research published by corporate entities, such as private consultancy firms.
Cross-national academic research	Cross-national research published by academic institutions, such as an academic journal article.
Cross-national government research	Cross-national research published by government institutions, such as government-commissioned reports.

Official statistics	Data from official institutions, such as national accounts from a country's central bank.
Official survey data	Survey data from official institutions, such as household finance surveys from a country's national statistical office.
Corporate research	Research published by corporate entities, such as private consultancy firms.
Academic research	Research published by academic institutions, such as an academic journal article.
Government research	Research published by government institutions, such as government-commissioned reports.
Government legislation	The actual text of public legislation.
Government legislative info	Texts published by government institutions that provide descriptive information about public legislation, such as a government website explaining tax clauses.
Government documents	Other texts published by government institutions, such as tax documents, forms, or descriptive reports.

Each source estimates inequality indicators using different types of data, such as household surveys, administrative data, and national accounts. To track these differences, we categorize each source according to the type of data used, as detailed in the taxonomy listed in Table 4.7.

As the data type classification is source-specific, the exercise of assigning a type to each source turns out to be less precise for cross-national sources, as we do not differentiate across countries specificities within the same source. For instance, in the case of the Luxembourg Wealth Study Database [53] and the OECD Wealth Distribution Database [57], we classify the data type as *Household survey*. However, data for one country, Norway, does not come from a wealth survey but from various administrative sources. Similarly, we classify the World Inequality Database [94] as a *Mix of sources and methods* to reflect the variety of data sources and estimation methods underlying this source. All these details features in the source-specific **Methodological Table**.

Eventually, once the relevant source is identified and correctly classified, we acquire the raw data.

For sources classified as Cross-national official survey data, we produce our own estimates starting from micro data. In these cases, only the resulting statistics are made available in the warehouse, without releasing

Table 4.7: Data Type

Label	Description
Household survey	The series has been estimated using only household survey data.
Wealth survey	The series has been estimated using only wealth survey data.
Household survey (with adjustments)	The series has been estimated from household survey data that has been adjusted, especially at the top. Adjustment methods comprise rich-list based adjustment als well as pure reweighting methods.
Household survey and national accounts	The series has been estimated using houehold survey data that has been brought into alignment with macroeconomic balance sheets.
Rich list	The series has been estimated using only rich list data points.
Capital income tax data, household survey, and national accounts	The series has been estimated via a capitalization approach that uses data on income due to the ownership of wealth (capital income), supported by survey data, and the series aligns with macroeconomic balance sheets.
Capital income tax data, other sources, and national accounts	The series has been estimated via a capitalization approach that uses data on income due to the ownership of wealth (capital income), additional data other than household survey data, and the series aligns with macroeconomic balance sheets.
Inheritance/estate tax-based	The series has been estimated via a mortality-multiplier approach using inheritance and/or estate tax data.
Inheritance/estate tax data, household survey, and national accounts	The series has been estimated via a mortality-multiplier approach using inheritance and/or estate tax data, supported by survey data, and the corresponding aggregates align with macroeconomic balance sheets.
Wealth tax/register-based	The series has been estimated from wealth tax data or register data on wealth.
Wealth tax/register data and estate tax data	The series has been estimated from wealth tax data or register data on wealth used in conjunction with estate/inheritance tax data.
Wealth tax/register data, other sources, and national accounts	The series has been estimated from wealth tax data or register data on wealth in conjunction with additional sources other than estate/inheritance tax data, and it has been brought into alignment with macroeconomic balance sheets.
Mix of sources and methods	Any series that rely substantively on a combination of sources and methods and that cannot be listed under any of the other classifications.

the underlying micro data. The code to produce the estimates for each source from the raw micro data is publicly available. Researchers interested in replicating the estimates we provide, should independently request access to the raw micro data from the original data provider. These sources are: Demographic and Health Surveys [81], Global Findex Database [33], WAEMU Harmonized Household Living Conditions Surveys [87], Household Finance and Consumption Survey [43], Living Standards Measurement Study [86], and Luxembourg Wealth Study Database [53]. For all other sources, we use the raw data as published.

4.5.2 Step 2: Transformation and Harmonization of Raw Data

The published raw data may come in various shapes or formats, including .pdf documents, and .xlsx or .csv files. Therefore, we need to process this information and harmonize the source-specific series to conform to the warehouse standards. This involves assigning each data point (`value`) with relevant information, including its data source (`source`), reference year (`year`), country code (`GEO`, `GEO_long`), type of inequality indicator (`varcode`), and the percentiles of the distribution it represents (`percentile`). This procedure ensures a consistent data structure across all sources. If feasible, we derive additional indicators from the available data. For example, if a source provides estimates for the wealth share of the richest 1% (p99p100) and the wealth share of the richest 10% (p90p100), we calculate the wealth share of the Next 9% (90th–99th percentiles) based on these estimates. It is important to note that when a source provides multiple estimates for the same inequality series, we select only one of these values, typically the benchmark estimate as defined in the underlying research paper or database. In future releases of the GC Wealth Project, we aim to explore the within-source variation of wealth inequality estimates by incorporating the full range of estimates that reflect different methodological assumptions. Finally, the current version of the Wealth Inequality database does not publish fully imputed estimates of wealth inequality. An estimate is defined as fully imputed if no wealth distribution data was used in the estimation of wealth inequality indicators for a specific country. Wealth distribution data may derive directly from micro-level data or from databases that publish wealth inequality measures estimated on the basis of micro data. This definition implies that the database still includes time series in which wealth distribution data has been used only in one or selected years, with missing years filled through interpolation. This has implications for a handful of sources, such as Credit Suisse [30] and the World Inequality Database [94], which are discussed in the Appendix (Section C.3).

4.5.3 Step 3: Testing and Appending

After making sure the acquired, derived, and estimated wealth inequality indicators follow our formatting standards, we run a set of consistency checks and tests before we append them to the Wealth Inequality

database.

4.6 Methodological Tables

The **Methodological Tables** summarize for each source, among other things: the type of data used, where the work sources its data, the unit of analysis, the methods of estimation, how different assets are valued, how specific types of assets are treated, any adjustments made to the data, important underlying assumptions, and more. We provide a brief description of the content of the **Methodological Tables** in Table 4.8.

Table 4.8: Methodological Tables - Content Description

Field name	Field description
Legend	The name of the source.
Period covered and data points	The range from the first to last year included in the series published in the warehouse; the precise years and/or quarters for which data points are available; the total number of years and/or quarters containing data points.
Data type	A categorization of the data type(s) used in the series published in the warehouse.
Inequality indicators	The precise inequality measures covered in the series. See the description of the varcode (vartype) for more information on these measures.
Data sources used in the research	A list of all data sources used in the estimation of wealth inequality and the year(s) they provide data for. Note that not all of these data sources are necessarily relevant to the specific series we publish in the database. Full citation information for these sources is not typically included in the references section, and should instead be located from the source itself.
Unit of analysis	The unit of analysis of the series published in the warehouse. See the description of the varcode (dashboard-specific) for details.
Definition of wealth	The precise definition of wealth underlying the wealth inequality estimates provided by the source.
Method of estimation	A brief summary of the estimation method of the series published in the warehouse.
Method of estimation (detailed)	A more detailed explanation (when applicable) of the estimation method of the series published in the warehouse.
Valuation of assets	How specific assets and liabilities have been valuated.
Treatment of private pensions	Whether any private pensions are included in the wealth definition, and if applicable, how they have been valuated.
Treatment of public pensions	Whether any public pensions are included in the wealth definition, and if applicable, how they have been valuated.
Treatment of life insurance	Whether any life insurance benefits are included in the wealth definition, and if applicable, how they have been valuated.

Treatment of household and personal goods (e.g., vehicles, boats, aircraft, jewelry, antiques, works of art, collections)	Whether any valuables and consumer goods are included in the definition of wealth, and if applicable, how they have been valuated.
Treatment of foreign wealth holdings	Whether any assets held abroad are included in the wealth definition, and if applicable, how they have been valuated.
Treatment of debt	Which types of liabilities are included in the wealth definition, and if applicable, how they have been valuated.
Adjustments to data	An explanation of any significant adjustments made to the raw data.
Distributional estimates aligned with national account aggregates	Whether the wealth estimate has been brought into alignment with the reference country's national accounts wealth aggregates.
Total population estimate and source	The manner and source of the reference population estimate underlying the series.
Total wealth estimate and source	The manner and source of the aggregate wealth estimate underlying the series.
References	A bibliography for the sources cited parenthetically in the table's analysis (i.e., not necessarily those listed in the data sources used in the research section). Any important references that are called out by title in the analysis (such as appendices, data files, or a working paper version of the source) are listed first, with their reference information and any downloadable files being available at their hyperlinked entry in the Data Sources Library.

4.7 Wealth Inequality Section — Innovative Features of Version 2.0 of the Warehouse

Version 2.0 of the Wealth Inequality section introduces two innovations with respect to earlier versions of the warehouse: the Distributional Topography module and the Asset and Liability Ownership Rates module.

4.7.1 The Distributional Topography Module

The Distributional Topography module aims to provide estimates of wealth portfolios across the net wealth distribution. Rather than focusing solely on aggregate inequality indicators, this module documents how the composition of assets and liabilities varies across different segments of the distribution, offering a more granular picture of wealth structures.

The module builds on the Distributional Wealth Accounts published by the European Central Bank [@ EuropeanCentralBank2024_DistributionalWealthAccounts] and on the Distributional Financial Accounts published by the Federal Reserve (FED) [64], which both provide breakdowns of asset holdings by position in the wealth distribution. We complement and extend these estimates by integrating micro data from the Luxembourg Wealth Study Database (LWS) [53] and the Household Finance and Consumption Survey (HFCS) [43], thereby broadening both the country coverage and the level of detail potentially available.

To ensure comparability across sources, we decompose the net wealth (`varcode` concept `netwea`) held by different wealth sub-populations into Financial Assets & Fixed Capital of Personal Businesses (`nnhass`), Housing & Land (`nfahou`), where available durables (`nfadur`), and Debt (`fliabi`). For each of these assets and liabilities, we provide averages (`avg`), totals (`tot`), and assets shares on total net wealth (`dsh`) held by the sub-group of the population indicated in the variable `percentile`. As in the rest of the warehouse, data on monetary units (averages and totals) are always shown in national currency, in nominal terms with no adjustment for inflation. The supplementary variables (see Section 2.2) can be used to transform all monetary values into other currencies and to adjust for inflation.

To better illustrate the functioning of the module, Table 4.9 presents a selection of estimates from the Distributional Topography module for Italy (IT) in 2024, sourced from the ECB Distributional Wealth Accounts (ECB_DWA_ineq). All observations refer to the bottom 50% of the wealth distribution (p0p50), with households as the unit of analysis (ho).

The varcode follows the structure `t-hs-[Variable Type]-[Concept]-ho`. Two variable types are shown: averages (`avg`) and shares (`dsh`). For each, net wealth (`netwea`) is decomposed into Housing & Land (`nfahou`),

Table 4.9: Distributional Topography: Italy 2022, ECB DWA, Bottom 50%

Varcode	Percentile	Value
t-hs-avg-fliabi-ho	p0p50	-23740.000
t-hs-avg-netwea-ho	p0p50	63950.000
t-hs-avg-nfahou-ho	p0p50	64350.000
t-hs-avg-nnhass-ho	p0p50	23330.000
t-hs-dsh-fliabi-ho	p0p50	-2.770
t-hs-dsh-netwea-ho	p0p50	7.463
t-hs-dsh-nfahou-ho	p0p50	7.511
t-hs-dsh-nnhass-ho	p0p50	2.722

Financial Assets & Fixed Capital of Personal Businesses (`nnhass`), and Debt (`fliabi`).

For example, the row with `varcode t-hs-avg-netwea-ho` indicates that the average net wealth of households in the bottom 50% is 63,950 (in nominal national currency), which can be further decomposed into an average of 64,350 in Housing & Land, 23,330 in Financial Assets & Fixed Capital, and 23,740 in Debt.

Similarly, the row with `varcode t-hs-dsh-netwea-ho` indicates that the net wealth held by households in the bottom 50% of the net wealth distribution amounts to approximately 7.46% of aggregate net wealth. The corresponding decomposition reveals that the Housing & Land held by this group is worth 7.51% of aggregate net wealth, while their Financial Assets & Fixed Capital of Personal Businesses account for only 2.72% of aggregate net wealth, suggesting that the wealth portfolio of the bottom half is overwhelmingly concentrated in real assets rather than financial ones.

Formally:

$$\text{dsh}_{c,p} = \frac{\text{tot}_{c,p}}{\text{tot}_{\text{netwea},\, p0p100}} \times 100 \tag{4.1}$$

where $c \in \{\text{netwea}, \text{nfahou}, \text{nnhass}, \text{fliabi}\}$ denotes the asset concept, p denotes the percentile group, $\text{tot}_{c,p}$ is the total value of concept c held by the population in percentile group p, and $\text{tot}_{\text{netwea},\, p0p100}$ is the aggregate net wealth of the entire population. Note that the within-asset-class share — i.e., the fraction of total concept $c held by percentile group $p — can be recovered as:

$$\frac{\text{tot}_{c,p}}{\text{tot}_{c,p0p100}} = \text{dsh}_{c,p} \times \frac{\text{tot}_{netwea,p0p100}}{\text{tot}_{c,p}} \tag{4.2}$$

4.7.2 The Asset and Liability Ownership Rates module.

The Asset and Liability Ownership Rates module provides survey-based estimates of ownership rates for countries where conventional wealth data are not available. In particular, the module leverages a series of micro data and statistics produced through international programs designed to generate harmonized, cross-nationally comparable data. These programs include the Demographic and Health Surveys Program, the World Bank's Living Standards Measurement Study Program (LSMS) and Global Findex Database, and the joint initiative by of the World Bank and the West Africa Economic and Monetary Union's "Harmonized Survey on Household Living Conditions (EHCVM)". The sources used are: Demographic and Health Surveys [81], WAEMU Harmonized Household Living Conditions Surveys [87], Living Standards Measurement Study [86], and the Global Findex Database [33].

The Asset and Liability Ownership Rates module fills a critical gap in global wealth measurement by providing survey-based estimates of asset ownership rates for countries where conventional wealth data are unavailable. Low and Middle Income countries are typically underrepresented in global analyses of wealth, due to the scarce availability of complete wealth data. In low- and middle-income countries, housing and land are often the most significant assets held by households, especially where financial inclusion remains low. Capturing ownership of these assets, alongside deposits, is therefore an important first step to understanding household wealth in developing economies. Crucially, the inclusion of this module extends the country coverage of the GC wealth Project's data warehouse by 111 countries, significantly expanding the geographic reach of the GC wealth database into low- and middle-income settings.

Table 4.10 reports, for each source, the country coverage and the core asset classes included in the Wealth Inequality warehouse. To allow for comparisons with countries where richer wealth data are available, we also compute ownership rates from the Luxembourg Wealth Study Database (LWS) [53] and the Household Finance and Consumption Survey (HFCS) [43].

4.8 Additional Information on the Wealth Inequality Section

For additional information about the Wealth Inequality section, we refer the reader the to the Appendix of this Documentation, where we provide a list of all sources included in the Wealth Inequality database, country-specific information on the coverage of the Wealth Inequality database, and additional information on the precise treatment of selected sources.

Table 4.10: Wealth Inequality: Ownership Rates Sources

Source	Legend	Areas	Concepts
DHS_ineq	Demographic and Health Surveys (own estimates)	AF, AL, AM, AO, AZ, BD, BF, BI, BJ, BO, CD, CG, CI, CM, CO, DO, EG, ET, GA, GH, GM, GN, GT, GY, HN, HT, ID, IN, JO, KE, KG, KH, KM, LR, LS, MA, MD, MG, ML, MM, MR, MV, MW, MZ, NE, NG, NP, PE, PG, PH, PK, RW, SL, SN, ST, SZ, TD, TG, TJ, TL, TR, TZ, UA, UG, YE, ZM, ZW, NA	fadepb, nfaala, nfhous

Section 5

Taxes on Wealth

5.1 Introduction to the Taxes on Wealth Section

This chapter introduces the reader to the data structure of the Taxes on Wealth section, as well as the general interpretation and construction of each concept. The Taxes on Wealth section of the GC Wealth Project provides a comprehensive data collection on wealth transfer taxes across countries and over time. The section compiles estate, inheritance, and gift (EIG) tax policy information as well as tax revenue data. It contains information about EIG taxes for over 200 countries (202 countries and 51 U.S. states, including District of Columbia), in some instances dating back as far as the 18th century. The section codifies and harmonizes information on common features, such as introduction and repeal dates, top tax rates, personal tax exemptions, number of brackets, full tax schedules, tax revenues, information on exempted assets, and heterogeneous tax treatment by degree of kinship. Information is obtained from academic, government, and corporate research, government legislation and legislative information, as well as cross-national research and official statistics. Table 5.1 below reports a comparison of the information available in the dataset with respect to other sources:

5.2 Data Structure and Interpretation

Downloaded data is provided in long format. All information in the data is sorted by a country's two-letter ISO code (`GEO`), or its full name (`GEO_long`) and `year`. The combination of `GEO-year` and `varcode` identifies univocally the value corresponding to a given information specified by the varcode for that GEO-year (see Table 5.6 for an example).

Table 5.1: Comparison of different taxation databases

Feature	Scheve and Stasavage (2012)	Seelkopf et al. (2021)	Genschel et al. (2023)	OECD (2021)	Our new database
Time Coverage	1816-2000	1750-2018	1880-2015	2015	1759-2025
Country Coverage	19 'core'	220	87	28 (OECD)	202
Top marginal tax rates	Y	Partial	N	Y	Y
Exemption Threshold	N	N	N	Y	Y
Full tax schedule	N	N	N	Partial	Y
Tax revenue	N	N	Partial	Y	Y
Introduction & repeal dates	N	Partial	Y	Partial	Y
EIG tax status	N	N	Y	Y	Y
Separate information about EIG taxes	N	N	N	Y	Y
Sub-national tax features	N	N	N	Partial	Partial
Detailed information on exempted assets	N	N	N	Y	Partial
Information on relationship-based tax features	N	N	N	Y	Y

5.2.1 General assumptions

To enhance cross-country comparability, we assume that tax treatment applies to taxable asset transfers, assuming no additional circumstantial deductions, reliefs, or credits apply unless otherwise specified in the Note variable[1]. Moreover, in the main variables we do not take into account any additional mitigating factors – like higher exemptions or lower rates for minors or disabled children, while citing those in the Note.

Since tax reforms can be approved any time in a year, we follow the general rule of applying the reform from the year in which it is approved. However, if the law clearly specifies the starting date, then we follow the timing established by law. For example, Sweden unified inheritance and gift tax was abolished in 2004, but the law clarifies it applies to transfer after 31 December 2004 and death-transfers after 17 December 2004; therefore, the database reports no tax for Sweden from 2005 onwards.

The data warehouse includes sub-national information about the U.S. states, harmonized and included directly in the data. For the U.S. states, while the status variable is related to each single state, all the other main variables (e.g., top marginal tax rate, exemption threshold) are reported considering the interaction between state and federal-level taxation (details in section 5.3). It follows that if some States (e.g., Alabama, Arizona, South Carolina) do not levy any EIG tax, then they have a corresponding status 0 (No) in the data, but

[1] When relevant, we use the rates for the statutory shares (e.g., Luxembourg). If an inheritance tax is levied, but the exemption is based on the entire estate (e.g. in Japan), we specify it in the Note.

reporting the positive federal top marginal tax rate and exemption threshold.

Additional subnational information for other countries is available in the Note. When a country-level EIG tax is not levied, but there are different regional tax schemes (e.g., Belgium, Switzerland, Brazil, and Canada), we report the national/federal information and detail in the Note if a subnational taxation is enforced, together with possible other information about the regional taxation rules. For countries with a colonial history that introduced a tax during the colonial period - thereby applying the tax of the mother country - the first year of introduction used is the year of independence if the new-born state retained the tax, and we specify in the Note if the tax was in effect during the colonial period.

To guarantee harmonization and comparability over time, all monetary values (e.g. exemption thresholds, tax brackets, tax revenues) are converted in the local currency unit in force in June 2026 as reported in the World Inequality Database.

There are cases in which wealth transfers are taxed through taxes different than EIG taxes (e.g. through the personal income tax); in these cases, we report that there is no EIG tax for the relevant wealth transfer – i.e. status = 0 – and use a dedicated variable indicating whether the wealth transfer is taxed through a different type of tax. If available, we specify which type of tax in the Note (See 5.2.6.1 for details).

In the cases in which a gift tax applies on a lifetime basis only at the death of the donor (currently in the U.S., from 1822 to 1987 in Brazil), or is levied only on donations occurred in a specific range of years before the death of donor (7 years currently in the U.K., 3 years from 1962 to 1999 in Cyprus), we report that a gift tax is levied (`status` is 1) and provide the details in the Note.

5.2.2 Sources hierarchy

The Taxes on Wealth section version 2.0 provides a single source for each country-year-tax feature combination, selected according to hierarchical criteria among the available sources.[2] When all sources agree, we rely on the source with more complete information on different tax features in a given year. When multiple sources agree on a given tax feature, we give priority to the source covering the longest period. If multiple sources agree on both features and time horizon, we give priority to official legislative sources. In the event of conflicts and inconsistencies between different sources, we report the information deemed most reliable because it is consistent with other information for the same country in different years, or because it is reported by more than one source, and we report the discrepancy in the Note.

As an example of conflict management, for the inheritance taxation of non-relatives in France between 1832

[2]State-specific data for the U.S. states are an exeption and have a list of sources for each data point.

and 1900, [71] reports a flat rate of 9% from 1833 to 1849, and of 11.5% from 1850 to 1900, while [41] report a flat rate of 5% for the same group from 1798 to 1900. Since [71] is a more detailed source, reporting the tax rate also for all the degrees of kinship, while [41] only reports the top rate for non-relatives, we rely on [71] for the years of conflict. As a second example, for the estate tax in the U.K. in 2011, [36] reports a flat rate of 40% above an exemption of GBP325,000 with no difference by kinship, and a similar configuration also for previous years (2006-2010). However, [52] explicitly report full exemption for spouses (in force since 1975). Therefore, we separate spouses from the other degrees of kinship and report separate schedules.

5.2.3 The `varcode` in the Taxes on Wealth Section

As described in the general warehouse structure section, the `varcode` uniquely identifies each value in the Taxes on Wealth section using five elements: the section, the sector, the type, the concept, and a bracket id. Hence, the `varcode` takes the following form:

$$\underbrace{x}_{\text{Section}} - \underbrace{BB}_{\text{Sector}} - \underbrace{CCC}_{\text{Variable Type}} - \underbrace{DDDDDD}_{\text{Concept}} - \underbrace{ZZ}_{\text{Section Specific}}$$

The first element is a 1-digit code that identifies the section of the GC Wealth Project, which for the case of the Taxes on Wealth takes the value x. The sector element – BB – indicates the tax (first letter) and the group of individuals on which the tax is levied (second letter). The following three digits – CCC - refer to the nature of the variable, while the six digits DDDDDD represent the concept of interest. The last two digits – ZZ – allow to identify each specific tax bracket, when applicable.

5.2.4 `Sector`: type of tax and affected groups

The EIG sector is identified by a combination of two informative letters. The first letter indicates the type of tax: `e` stands for estate, `i` for inheritance, and `g` for gift tax. We use `t` as the first letter as *transfer* to denote general wealth transfers, applicable to total EIG tax revenues only (e.g. resulting from the sum of revenues of all inheritance, estate, and gift taxes applicable in a given country). The second letter denotes the population group subject to taxation: `e` for everyone (indicating the tax affects everyone regardless of the degree of kinship); `c` for children (meaning the tax is levied on the children of the donor/decedent); `s` for spouse; `l` for siblings; `r` for relatives different from children, spouse and siblings; `n` for non-relatives. Table 5.2 provides more details of the classification used for parental kinship (e.g. parents and grandparents are included in the `c` category). When the source does not report to which degree of kinship a specific tax schedule applies, the second letter is `u` for *unknown*. Lastly, to refer to tax revenues, which do not belong

to any specific group, we use g for *general* as second letter. As a general rule, in case of an estate tax, the tax schedule is the same regardless the degree of kinship. However, there are notable exemptions, like the U.K. and the U.S.: in case some categories, as children or spouses, have preferential tax treatment, then a classification by degree of kinship is possible also for the estate tax.

Table 5.2 summarizes the sector combinations.

Table 5.2: EIG: Sector

Code	Label	Description
tg	EIG Tax, general government level	The tax revenue information refers to the sum of estate, inheritance and gift taxes (EIG) for the general government sector.
gg	Gift Tax, general government level	The tax revenue information refers to gift tax for the general government sector.
ec	Estate Tax for Children	Estate tax levied on children of the donor/decedent. The group also includes grandchildren, parents and grandparents, unless otherwise stated in the note.
es	Estate Tax for Spouse	Estate tax levied on the spouse of the donor/decedent. The group includes the legal cohabitant unless otherwise specified in the note.
el	Estate Tax for Siblings	Estate tax levied on the siblings of the donor/decedent. The group also includes children of siblings, unless otherwise stated in the note.
er	Estate Tax for Other Relatives	Estate tax levied on the relatives of the donor/decedent, excluding spouse, children, and siblings.
en	Estate Tax for Non-Relatives	Estate tax levied on individuals who are not related to the donor/decedent.
ee	Estate Tax for Everybody	Estate tax levied on anyone regardless of the degree of kinship or relationship to the deceased/donor. This sector is used also if the estate tax is not levied.
eu	Estate Tax, applies to unknown	The population group to which the estate tax applies is not known from the sources available.

Table 5.2: EIG: Sector *(continued)*

Code	Label	Description
ic	Inheritance Tax for Children	Inheritance tax levied on children of the donor/decedent. The group also includes grandchildren, parents and grandparents, unless otherwise stated in the note.
is	Inheritance Tax for Spouse	Inheritance tax levied on the spouse of the donor/decedent. The group includes the legal cohabitant unless otherwise specified in the note.
il	Inheritance Tax for Siblings	Inheritance tax levied on the siblings of the donor/decedent. The group also includes children of siblings, unless otherwise stated in the note.
ir	Inheritance Tax for Other Relatives	Inheritance tax levied on the relatives of the donor/decedent, excluding spouse, children, and siblings.
in	Inheritance Tax for Non-Relatives	Inheritance tax levied on individuals who are not related to the donor/decedent.
ie	Inheritance Tax for Everybody	Inheritance tax levied on anyone regardless of the degree of kinship or relationship to the deceased/donor. This sector is used also if the inheritance tax is not levied.
iu	Inheritance Tax, applies to unknown	The population group to which the inheritance tax applies is not known from the sources available.
gc	Gift Tax for Children	Gift tax levied on children of the donor/decedent. The group also includes grandchildren, parents and grandparents, unless otherwise stated in the note.
gs	Gift Tax for Spouse	Gift tax levied on the spouse of the donor/decedent. The group includes the legal cohabitant unless otherwise specified in the note.
gl	Gift Tax for Siblings	Gift tax levied on the siblings of the donor/decedent. The group also includes children of siblings, unless otherwise stated in the note.
gr	Gift Tax for Other Relatives	Gift tax levied on the relatives of the donor/decedent, excluding spouse, children, and siblings.

Table 5.2: EIG: Sector *(continued)*

Code	Label	Description
gn	Gift Tax for Non-Relatives	Gift tax levied on individuals who are not related to the donor/decedent.
ge	Gift Tax for Everybody	Gift tax levied on on anyone regardless of the degree of kinship or relationship to the deceased/donor. This sector is used also if the gift tax is not levied.
gu	Gift Tax, applies to unknown	The population group to which the gift tax applies is not known from the sources available.

5.2.5 `Variable Type`

Six types of variables are used within the Taxes on Wealth section. These are described in Table 5.3.

Table 5.3: EIG: Variable Type

Code	Label	Description
rat	Rate	In general, a rate is expressed as a percentage. For instance, the marginal inheritance tax rate is the amount of tax that is paid on an additional dollar of inheritance received. It represents the rate at which a person's tax liability increases as their inheritance increases. The concept can also be applied to the saving rate which refers to the percentage of disposable income that is saved or not spent on consumption.
rto	Ratio	A ratio describes the relationship between two quantities and is expressed as the quotient of one quantity divided by another. For example, if a country's total private net wealth is €10,000 billion and its total national income is €2,000 billion, the ratio of private wealth to national income is 5 to 1, as total private wealth is five times the amount of national income.

Table 5.3: EIG: Variable Type *(continued)*

Code	Label	Description
thr	Threshold	A threshold represents a minimum or maximum value that must be met or exceeded, for instance, the minimum value of net wealth that is needed for an individual to belong to the group of the richest 1% of adults, or the maximum value of net wealth that is needed for an individual to belong to the group of the poorest 50% of adults.
cat	Categorical Variable	A categorical variable represents data that can be divided into groups or categories.
tot	Total	It represents the total value of a variable. For instance, total population, or total revenue raised from the inheritance tax.
per	Period	Numeric values that refer to a period (year, month, quarter).

5.2.6 `Concept`: Variables

The next six letters indicating `Concept` encode the specific variables for this section (see Table 5.5 for details). These variables can refer to the status of a tax - whether it is levied or not, directly or indirectly through a different tax -, the characteristics of the tax (progressivity, top rate, exemption, full tax schedule), and the associated tax revenue information.

5.2.6.1 Tax status, and bracket-invariant concepts

The database contains nine bracket-invariant information related to a specific tax, namely the status (`status`), an indicator for whether the tax is not levied directly but rather through another tax (`different_tax`), the first year the tax has been levied in the country (`firsty`), the type of tax (`typtax`), the exemption threshold (`exempt`), the top marginal tax rate (`toprat`), the top marginal rate lower bound (`toplbo`), an indicator for whether the home residence is exempt from the tax (`homexe`), and an indicator for whether the family business is exempt from the tax (`bssexe`).

The binary variable `status` is used to indicate whether a country or region levies the transfer tax specified in the first digit of the sector code (estate, inheritance, or gift). Status can take either value 1 (Yes) or 0 (No).

Countries for which no data is available other than the tax revenue from the OECD are marked as not having

an estate, inheritance, or gift tax if the OECD revenue statistics report zero revenues. These cases are marked as "Inferred from OECD" in their Source variable.

If wealth transfers are taxed through taxes different from proper EIG taxes (e.g. through either the capital or the personal income tax), we report that there is no EIG tax for the relevant wealth transfer – i.e. `status = 0` while `different_tax = 1`, and the Note variable reports the corresponding additional details. For example, since 2014, the gift tax in Czech Republic has been included in the personal income tax. Therefore, the gift tax status equals 0, the `different_tax` variable is equal to 1, and the Note variable reports the corresponding additional details. . Table 5.4 reports the countries and years for which a different tax applies in the database.

Table 5.4: Countries where inheritance and/or gifts are taxed through other taxes

Country	From	To	Note
Albania	1913	2023	Inheritance tax is implemented through taxation on income.
Azerbaijan	2006	2025	Azerbaijan taxes inheritances and gifts through the personal income tax, with full exemption for family members and below AZN 20,000.
Botswana	2006	2023	In Botswana, the Capital Transfer Tax (CTT) is a tax levied on the transfer of assets through inheritance, donations, or other gratuitous dispositions. The exemption of BWP 100,000 of inheritances and gifts is inferred for all other relationships except spouses as they are fully exempt. Moreover, the CTT consists of tax on lower amount + rate on excess. So, the schedule is (0,100000,300000,500000,_and_over), marginal rates are 2,3,4,5 and the tax on lower amount is (0,2000,8000,16000) following the same schedule and rates.
Canada	1972	2024	Capital gains tax implications arise from deemed dispositions of property at death or when property is gifted. These rules are uniformly applied, with specific deferrals and exceptions, particularly for spousal transfers and certain types of trusts.

Table 5.4: Countries where inheritance and/or gifts are taxed through other taxes *(continued)*

Country	From	To	Note
Colombia	2006	2023	Capital gains are taxes at the fixed rate of 15%. The first 3250 UVT received from spouse or legal heirs (inferred as children and siblings) as a gift or inheritance is exempt from tax. According to law, in general inheritance and gifts are treated as non-recurring/occasional earnings, therefore, taxed under capital gain tax. Moreover, the first UVT 13,000 of urban and first UVT 6500 for rural real estate property received as a gift or inheritance by spouses and legal heirs is exempt from tax.
Costa Rica	2006	2023	Costa Rica does not have inheritance, gift, estate or succession taxes, but a tax on transfer of real property. By 2008, the rates are between 1 and 2% and divisions between spouses and joint owners are not taxable.
Czechia	2014	2024	As of January 1, 2014, gift tax is included in the income tax. Gifts and other income received without consideration are exempt from personal income tax if they come from a first- or second-degree relative (e. g. sibling, uncle, aunt, nephew, niece, spouse, stepchild, stepparent) or from someone with whom the taxpayer lived and shared household responsibilities for at least one year prior. Additionally, income up to CZK 50,000 per year from casual sources is exempt.
El Salvador	2006	2023	El Salvador does not impose separate estate or gift taxes. However, estates may be taxed as ordinary taxpayers if they derive income before the assets are distributed to the beneficiaries.
Georgia	2006	2023	Georgia does not impose inheritance and gift tax. However, both are subject to general income taxation. However, certain exemptions are applied.
Ghana	2016	2023	From 2016 to 2023, gifts are taxed as part of employment, business or investment income.
Guatemala	2006	2023	It is inferred that VAT 12% is levied on everybody for inter vivos gifts.

Table 5.4: Countries where inheritance and/or gifts are taxed through other taxes *(continued)*

Country	From	To	Note
Haiti	2004	2008	As of 2004 and 2008 a stamp tax at rate 1-8% depending on type of property and relationship between parts applied. Stamp tax rate for inter-vivos transfers ranged from 2%-9% depending on the nature of the relationship of parties.
Iceland	2006	2025	Gifts and donations are subject to income tax. Resident donees pay gift tax.
India	2004	2025	Gift tax is treated as part of income tax starting 2004. The donor is not taxed, but the recipient may be taxed on gifts depending on the value and the relationship to the donor. The first 50,000INR are exempt.
Indonesia	2013	2024	Indonesian Income tax law says that gifts from parents to children directly (or vice versa) and gifts received by religious, social, educational and other organizations who carry on small scale enterprise in which there is no relationship among parties concerned are not taxable and rest are taxed accordance to Income tax law (Gift Grant Tax).
Israel	2006	2023	Israel does not impose inheritance or gift taxes. Normally transfers by inheritance or gifts are subject to capital gain tax or land appreciation tax.
Jamaica	2006	2023	Jamaica has no estate tax but there is a transfer tax on the transfer of land and shares in a jamican company on transfer by death. The exemption is J$ 100,000 (2006 to 2018) and J$ 10,000,000 (2019-2023). The transfer tax is 1.5%, 4%, 5%, 7.5%, for (2011-2023), 2010, 2009, and (2008- 2006) respectively.
Kosovo	2013	2023	Kosovo does not impose estate, inheritance, or gift taxes. However, gifts exceeding EUR 5,000 in a tax period are considered income and subject to income tax, therefore, different tax =1. Gifts between spouses, parents and children (in either direction) are exempt, regardless of value. Tuition payments made directly to recognized educational institutions are also tax-exempt, irrespective of the donor-recipient relationship.

Table 5.4: Countries where inheritance and/or gifts are taxed through other taxes *(continued)*

Country	From	To	Note
Malta	2014	2024	In the absence of descendants, siblings (and their descendants) are also fully exempt. There is no gift tax in Malta. Nevertheless, from an income tax perspective, the definition of a transfer put forward by the Income Tax Act, Cap. 123 of the Laws of Malta (ITA) encompasses donations. Therefore, donations of chargeable assets, including immovable property, business, intellectual property, securities in companies, interest in a parthership and a beneficial interest in a trust fall within the purview of income tax on capital gains. In case of immovable property situated in Malta or any right thereon, the property transfer tax (PTT) would apply instead. Any deemed capital gains derived from a taxable donation would be amalgamated with the donors other income and brought to charge at progressive tax rates from 0% to 35%. The default rate of PTT is 8%, and it is levied on the transfer value of the immovable property.
Mexico	2013	2024	Gifts are taxed through personal income tax with full exemption for children and spouse according to Mexican Income Tax Law.
Nicaragua	2013	2023	Gifts and inheritances from Nicarguan sources are treated as capital gain and are subject to flat 15% tax. It is inferred that this 15% flat tax is for all categories.
Singapore	2012	2024	Formally, gift taxation operates through a Stamp Duty, which treats gifts as a conveyance or transfer on sale of any immovable properties. New rates are effective from 15 February 2023.
Thailand	2006	2015	Gifts other than made on limited occassions or ceremonials are taxed through ordinary income.
Ukraine	2006	2024	According to Ukrainian law, a transfer of property - either inherited or received as a gift - is subject to personal income tax. Children, parents, spouse, grandchildren, grandparents and siblings are fully exempted, while for the others transfers are taxed at a 5% marginal rate.

Table 5.4: Countries where inheritance and/or gifts are taxed through other taxes *(continued)*

Country	From	To	Note
Uruguay	2006	2023	Transfer of real estate by gift or estate is subject to 4% transfer tax, except for inheritances from direct line of consanguinity, which is subject to a 3% transfer tax.
Viet Nam	2014	2025	Inheritances/gifts in excess of VND 10 million are subject to PIT at the rate of 10%. Spouse, children, and siblings are exempt.

When possible, the data further include a variable indicating the first year for which the wealth transfer tax has been levied in a country (`firsty`). When the first year is available, the series for that country starts from that year.

The variable `typtax` facilitates the users in recognizing whether a tax is lump-sum, flat, progressive by class, or progressive by brackets. The definition is based considering the number of brackets with positive marginal rates. If we do not observe the full schedule but a specific country-source clarifies the nature of tax under assessment, we are still able to fill the variable. Note that Germany has been levying since 1951 an inheritance tax with a progressive by class system, and Austria had the same approach from 1955 to 2007, when the tax was abolished.

Tax exemptions (`exempt`) can vary in complexity and detail, and countries differ in how they offer reductions to the final tax bill (exemptions, deductions, rebates, credits, etc.). Unless differently specified, the exemption is considered as a reduction of the tax base. In case the exemption has a different nature (e.g., tax credit as in the case of the U.S. from 1977), the exemption variable and the tax schedule are adjusted accordingly and details of the adjustments are reported in the Note variable of metadata. If a tax is levied, but there is no exemption, the variable exempt takes value zero. It may also happen that the tax is levied, but with full exemption for a certain group (typically children or spouse); in this case, `exempt` will take value -997 (_and_over) for that group. The exemption is expressed in local currency units.

When a tax exists, the top tax rate `toprat` is the marginal tax rate on the last bracket and typically takes positive values, unless a full exemption exists (zero `toprat`). On the contrary, it takes value zero when no tax is levied. The same logic applies to the lower bound threshold above which the top rate for the specified tax applies (`toplbo`). The top rate lower bound is expressed in local currency units.

Finally, `homexe` and `bssexe` are new variables of version 2.0. They can take values 0 and 1, or -998 (_na) if the tax is not levied. They indicate, respectively, whether the family home (i.e. the habitual abode) or the family business is exempt from taxation. All the details of such exemptions, when available, are reported in the Note.

5.2.6.2 Tax revenues

Tax revenues correspond to the 4300 (total EIG taxes) and 4320 (gift tax only) series of tax revenues from the OECD Revenue Statistics Database of the Organisation for Economic Co-operation and Development (OECD) (downloaded on August 2026). Revenues are reported in three different concepts: `revenu`, for the EIG tax revenues in local currency units; `prorev` stands for EIG tax revenues in percentage of total tax revenues; `revgdp` for the EIG tax revenues in percentage of GDP. Revenues information are available up to 2024 starting from 1965 for most of the OECD countries included, and from 1990 for most of the non-OECD countries.

5.2.6.3 Tax schedules

When the full tax schedule is available, it is identified by a set of tax brackets. These are a combination of three concepts: adjusted lower bound (`adjlbo`), adjusted upper bound (`adjbo`), and adjusted marginal rates (`adjmrt`). Therefore, each bracket identifies the amount of transfer above the `adjlbo` and below the `adjubo` to which the `adjmrt` applies.

Each bracket corresponds to a single GEO-year-varcode combination and is identified by the last two digits of the varcode.

Unless the tax is proportional, the schedules are typically cumulative in structure, such that the rate in a bracket that corresponds to a wealth transfer value only applies to the proportion of the transfer that is greater than the highest amount in the previous bracket. That is, if the transfer amount exceeds the previous tax bracket by one currency unit, the higher tax rate (of the following bracket) only applies to one currency unit. This structure of the tax schedule is summarized in the variable `typtax`.

We adjust the schedules to make them more comparable across countries. In particular, we modify the statutory schedule of each country to include the exemption as a first tax bracket with a zero marginal rate. Furthermore, we convert the bounds of the brackets to the most recent local currency unit, and merge the brackets with the same marginal rate to obtain the effective number of brackets. It is important to note that if the country levies a tax but applies a full exemption for direct heirs, we then follow an "economic effectiveness" principle and adjust the status and the corresponding tax schedule to be equivalent to a no-tax

scenario.

In the most common case in which the exemption is a reduction of the tax base, the adjustment consists in a shift of the tax brackets equivalent to the amount of the exemption. Differently, when the exemption is a tax credit, the adjustment consists in setting the amount of the tax credit as the new lower bound of the first bracket of the tax schedule and reporting zero marginal rate below it.

For instance, consider the U.S. federal estate tax: the statutory schedule contains a progressive schedule, but because the tax credit is so high (nearly 13 million USD as of 2023), every bracket but the last one is effectively within the tax credit range. Therefore (assuming no other deductions or credits apply), all amounts below (and many above) the last bracket would yield a final tax bill of zero. The result is a proportional tax rate that applies to relatively large estates of several million dollars[3].

All the concepts described above are summarized in the Table 5.5 here below.

Table 5.5: Taxes on Wealth: Variable Definitions

Code	Label	Description
status	Tax Indicator	Whether or not the country levies the specified tax for the given year. It is encoded as a 0/1 indicator variable.
diftax	Different Tax Indicator	Whether the EIG tax is levied through another type of tax (e.g., PIT, capital income, etc.).
firsty	First Year for Tax	The first year the specified tax is introduced in the country. It may predate the year of legal birth of the country, such as in the case of unified kingdoms or of former colonies.

[3]Note that this adjustment can affect also the variable `typtax`. For example, for the United States `typtax` is flat, although the statutory tax schedule is progressive

Table 5.5: Taxes on Wealth: Variable Definitions *(continued)*

Code	Label	Description
typtax	Type of Tax	The structure of the adjusted tax schedule, if applicable. The variable is encoded as follows: 1 lump-sum (fixed); 2 flat (proportional with a single rate applied to all tax base); 3 progressive (proportional with tax rates increasing with the tax base); 4 progressive by brackets (proportional with tax rates increasing with the tax base, with different portions of the tax base - brackets - taxed at different rates); -998 (_na) not applicable because the tax is not levied or there is full exemption. The type of tax is based on the number of positive tax rates included in the adjusted tax schedule.
exempt	Exemption Threshold	The exemption threshold in local currency units applicable to the sector, assuming no additional exemptions, credits or relief apply. It is reported as zero in case of no exemption, as -997 (_and_over) in case of full exemption (no tax is due), as -998 (_na) if it is not applicable because the tax is not levied.
toplbo	Top Marginal Rate Applicable From	The minimum amount in local currency units including and above which the top rate for the specified tax applies to the sector. It is encoded as zero in case the tax is not levied or there is full exemption.
toprat	Top Marginal Rate	The highest statutory rate for the specified tax. It is encoded as zero in case the tax is not levied or there is full exemption.
adjlbo	Lower Bound for Exemption-adjusted Tax Bracket	The value of tax base over which the tax rate applies in local currency units, adjusted to include the exemption amount in the tax schedule as a zero rate bracket, if needed.
adjubo	Upper Bound for Exemption-adjusted Tax Bracket	The highest tax base value for which the tax rate applies in local currency units, adjusted to include the exemption amount in the tax schedule as a zero rate bracket, if needed. It takes value -997 (_and_over) for the highest bracket if the interval is open.

Table 5.5: Taxes on Wealth: Variable Definitions *(continued)*

Code	Label	Description
adjmrt	Marginal Rate for Exemption-adjusted Tax Bracket	The rate of taxation on tax base values between the bracket lower bound and the bracket upper bound, adjusted to include the exemption amount in the tax schedule as a zero rate bracket, if needed. It is reported as zero in case the tax is not levied and for the exemption bracket.
homexe	Family Home Exempt	Whether the family home (i.e. the habitual abode) is exempt from taxation. It takes value -998 if it is not applicable because the tax is not levied.
bssexe	Family Business Exempt	Whether the family business is exempt from taxation. It takes value -998 if it is not applicable because the tax is not levied.
revenu	Total Revenue from Tax	Total revenue from the specified tax at all government levels in local currency units.
prorev	Total Revenue from Tax as % of Total Tax Revenue	Total revenue from the specified tax at all government levels as a percentage of total tax revenue.
revgdp	Total Revenue from Tax as % of Gross Domestic Product	Total revenue from the specified tax at all government levels as a percentage of GDP.

5.2.7 `Section Specific`: Bracket Numbers

Finally, the last two letters in the `varcode` denote the section-specific variables, which for the Taxes on Wealth section refer to the tax bracket number when needed. Full tax schedule information will vary by tax bracket, while bracket-invariant information is reported for the bracket "00" as illustrated in the example in Table 5.7.

5.2.8 An illustrative example

An example is illustrated in Table 5.6, reporting the main tax schedule and revenue information for the estate tax in the case of the U.S. in 2023. The example allows to visualize that each combination of `GEO-year` and `varcode` identifies univocally the value corresponding to a given information specified by the `varcode`. To further clarify, the value 1 in first row corresponds to the `varcode x-ec-cat-status-00` that indicates the status of the estate tax applicable to children.

Table 5.6: Simplified Illustration of the estate tax schedule for the U.S. in 2023 in long format

GEO	GEO_long	year	varcode	value	source	longname	note
US	United States	2023	x-ec-cat-status-00	1	IBFD	Categorical Variable Tax Indicator, of the Estate Tax for Children sector (Non-Bracket Specific)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-ec-per-firsty-00	1898	IBFD	Period First Year for Tax, of the Estate Tax for Children sector (Non-Bracket Specific)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-ec-rat-adjmrt-01	0	IBFD	Rate Marginal Rate for Exemption-adjusted Tax Bracket, of the Estate Tax for Children sector (Bracket n 01)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-ec-rat-adjmrt-02	40	IBFD	Rate Marginal Rate for Exemption-adjusted Tax Bracket, of the Estate Tax for Children sector (Bracket n 02)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.

Table 5.6: Simplified Illustration of the estate tax schedule for the U.S. in 2023 in long format *(continued)*

GEO	GEO_long	year	varcode	value	source	longname	note
US	United States	2023	x-ec-rat-toprat-00	40	IBFD	Rate Top Marginal Rate, of the Estate Tax for Children sector (Non-Bracket Specific)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-ec-thr-adjlbo-01	0	IBFD	Threshold Lower Bound for Exemption-adjusted Tax Bracket, of the Estate Tax for Children sector (Bracket n 01)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-ec-thr-adjlbo-02	1.292000e+07	IBFD	Threshold Lower Bound for Exemption-adjusted Tax Bracket, of the Estate Tax for Children sector (Bracket n 02)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-ec-thr-adjubo-01	1.292000e+07	IBFD	Threshold Upper Bound for Exemption-adjusted Tax Bracket, of the Estate Tax for Children sector (Bracket n 01)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-ec-thr-adjubo-02	-997	IBFD	Threshold Upper Bound for Exemption-adjusted Tax Bracket, of the Estate Tax for Children sector (Bracket n 02)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.

Table 5.6: Simplified Illustration of the estate tax schedule for the U.S. in 2023 in long format *(continued)*

GEO	GEO_long	year	varcode	value	source	longname	note
US	United States	2023	x-ec-thr-exempt-00	1.292000e+07	IBFD	Threshold Exemption Threshold, of the Estate Tax for Children sector (Non-Bracket Specific)	Since the US gift and estate tax are unified, gifts made during an individuals lifetime will reduce his or her estate tax exemption.
US	United States	2023	x-tg-rto-prorev-00	0.60	OECD_Rev	Ratio Total Revenue from Tax as % of Total Tax Revenue, of the EIG Tax, general government level sector (Non-Bracket Specific)	-
US	United States	2023	x-tg-rto-revgdp-00	0.15	OECD_Rev	Ratio Total Revenue from Tax as % of Gross Domestic Product, of the EIG Tax, general government level sector (Non-Bracket Specific)	-
US	United States	2023	x-tg-tot-revenu-00	4.273652e+10	OECD_Rev	Total Total Revenue from Tax, of the EIG Tax, general government level sector (Non-Bracket Specific)	-

To ease the users' understanding of the structure of the data, we also provide in Table 5.7 below a wide format transformation of the U.S. 2023 example. The wide transformation is particularly helpful to better understand and visualize the tax schedule of each country-year. In Table 5.7 we have the same information of the long format, but each column-title is the content of the `varcode`. In this case, we have an estate tax with

two effective tax brackets. The first bracket ranges between 0 and 12.9 million of dollars - the exemption level -, with a corresponding 0 marginal tax rate. The second bracket ranges from one dollar above the exemption threshold and over, with a marginal tax rate of 40%, which is the top marginal tax rate (`toprat`). Revenues information are available in the last three columns: `prorev`, `revgdp`, `revenu`. For example, the total revenues collected from the estate tax in 2023 is around 39 billion of dollars, corresponding to around 0.56% of the total revenues collected by the U.S. in 2023, and to 0.14% of the U.S. GDP in the year.

Table 5.7: Simplified Illustration of the estate tax schedule for the U.S. in 2023 in wide format

GEO	year	bracket	firsty	status	exempt	toprat	adjlbo	adjubo	adjmrt	revenu	prorev	revgdp
US	2023	0	1898	1	1.292000e+07	40	-	-	-	4.273652e+10	0.60	0.15
US	2023	1	-	-	-	-	0	1.292000e+07	0	-	-	-
US	2023	2	-	-	-	-	1.292000e+07	-997	40	-	-	-

5.3 Regional Information

Regional information for the United States - state-specific tax schedules - is directly available in the data from 2006. However, also other countries have regional taxation schemes; while we do not include them in the warehouse, we report the information in the Note variable and highlight below the main relevant cases of regional schemes.

Belgium:

Belgium does not levy EIG taxes at national level since 1989 [63], but the three regions - Flemish, Walloon, Bruxelles-Capital – can set their own taxes. Therefore, the data display a national EIG tax status equals to "0" (No) since 1989. Each region levies inheritance and gift taxes applying different rates. For example, taking the first child beneficiary as reference, the inheritance tax rate ranges between 3 and 30% in Bruxelles-Capital and Walloon regions; in Flemish region it ranges between 3 and 27%.

Brazil:

According to Carvalho Junior [31], and Tax Introduction Database [41], Brazil levies EIG taxes at state level since 1934. The act 27 of 1966 amended the tax law of 1965 (an Emenda Constitucional nº 18/1965) setting a federal level maximum top rate for gifts and inheritances to 2%. This maximum top rate was raised in 1988 to 8%. Therefore for Brazil the data display a national EIG tax status always equals to "0" (No).

Bulgaria:

In Bulgaria, the Law 117 of December 10, 1997 established that inheritance and gift taxes are levied at

municipality level. Therefore, there has been no national EIG taxation since 1998.

Spain:

EIG tax is a national tax in Spain, but there might be important differences between regions in terms of tax rates, reductions, and other benefits that significantly reduce the tax burden. Because of this, effective inheritance taxation is much higher under national law than under regional regimes. Furthermore, the autonomous regions of Navarre and Basque Country have a wide right to self-regulate gift and inheritance taxes. Taxation in these regions is significantly different from the national Spanish tax laws. We report the information on national taxation, but we include in the Note the available regional details.

Switzerland:

In Switzerland, the cantons have an exclusive right to set their own gift and inheritance taxes. According to EY [37, 35], the canton tax system has been applied since 2006. However, from 1973 to 2005, the EIG tax revenues are gathered at regional and local level according to the OECD Revenue data [58]. Therefore, we assume that the taxation was at the canton level even before 2006. The status for the national EIG taxation has been set to "0" (No) since 1973.

United States:

The data also include regional-level tax information for all U.S. states. Varcodes and variables for the regional level adhere to the database structure outlined above. In particular, `GEO` and `GEO_long` codes include the federal code/name followed by the state code/name, separated by an underscore.

We note some important conceptual differences for the interpretation of the regional information with respect to the national data. First, the `status` variable refers to the state-level, irrespective of federal taxes that also apply within state boundaries. Thus, if a given state indicates `status` = 0, the tax in the state can still be subject to the federal estate tax, if it applies. On the contrary, adjusted tax schedule variables combine full tax schedule information of federal- and state-level taxes. That is, EIG taxes levied by the state can provide adjustments of the statutory schedule depending on interactions with the federal tax. Thus, our state-level adjusted schedules take the joint structure of taxes at both levels into account in order to arrive at brackets amounts and marginal rates that are readily comparable across states within the U.S.

It may happen that a single U.S. state applies an inheritance tax. Since the federal tax is an estate tax, the interaction of the two schemes requires the assumption that the inheritance is received by a single direct descendant without siblings. For this reason, regional data for the U.S. are available only for the `children` group. Lastly, state and federal tax interactions can lead to marginal tax structures with spikes within the

tax bracket structure. Put differently, the highest tax rate in an adjusted schedule might not be the last bracket, and inheritances above that bracket will be subject to lower rates. In such cases, the top marginal tax rate still refers to the last bracket in the tax schedule rather than to the highest tax rate for consistency with the definition of the `toprat` and `toplbo` concepts.

Section 6

Inheritance Trends

6.1 Introduction to the Inheritance Trends Section

The Inheritance Trends section presents a comprehensive compilation of cross-national time-series data on the annual flow of wealth transfers, that is, the wealth passed from one household or individual to another either at the time of the donor's death (bequests) or while the donor is alive (inter vivos gifts). This section contains estimates of the size of these flows, expressed both in national currency and relative to national income, as estimated in the existing literature. It also documents the average effective rate at which these transfers are taxed.

The Inheritance Trends section is not about the distribution of wealth across the population: every estimate refers to the reference population as a whole. What it measures instead is the *magnitude* of the annual transmission of wealth between generations and its evolution over time. This distinction matters because inheritance flows are a macroeconomic quantity: they can be compared to national income, they can be traced back over long historical horizons, and they can be related to the tax revenue they generate.

The core value-added of this section is to assemble, for the very first time in a single venue, estimates that are otherwise scattered across national historical studies, each built on different records and conventions.

6.2 The Structure of the Inheritance Trends Section

In the Inheritance Trends database, each estimate (`value`) is uniquely identified by the combination of the reference country indexed by a two-digit identifier (`GEO`), the reference year (`year`), the data source (`source`),

Table 6.1: Introducing the GC Inheritance Trends Database - Snippet. Aggregates (`agg`) are reported in billions of national currency, in nominal terms; ratios (`rto`) and rates (`rat`) are reported in percent.

source	GEO	GEO_long	year	varcode	percentile	value
Acciari2021	IT	Italy	1995	i-hs-agg-etnwea-ff	p0p100	55.75

Guzzardi2026	IT	Italy	1996	i-hs-rto-etnweg-ef	p0p100	7.66

and the `varcode`.

Table 6.1 provides a small extract from the Inheritance Trends database. This table displays data for Italy in 1995 and 1996. The series reported in the `value` column correspond to an inheritance indicator (`varcode`), with the `percentile` column always set to *p0p100* because all estimates in this section refer to the reference population as a whole. The `varcode` column carries the substantive information: the type of measure (an aggregate in national currency, or a ratio to national income), the concept it refers to (bequests only, or bequests and gifts together), and the type of flow estimate (fiscal or economic). The subsequent sections elaborate on the `varcode` and on the `percentile` variable.

6.3 The `varcode` in the Inheritance Trends Section

In the Inheritance Trends section, two of the five elements of `varcode` are fixed across the entire database. The constant elements are the first, that identifies the Section of the GC Wealth Project and takes the value `i`, and the second, that indexes the household sector and takes the value `hs`. The `Variable Type`, the `Concept`, and the `Section-Specific` parts of the `varcode` vary within a source and across sources and are explained

in detail in what follows. Hence, `varcode` takes the following form:

$$\underbrace{i}_{\text{Section}} - \underbrace{hs}_{\text{Sector}} - \underbrace{CCC}_{\text{Variable Type}} - \underbrace{DDDDDD}_{\text{Concept}} - \underbrace{ZZ}_{\text{Section-Specific}}$$

6.3.1 `Variable Type`

The third element of the `varcode` identifies the broad type of measure. Table 6.2 provides the permitted strings of the `Variable Type` within the `varcode` in the Inheritance Trends database, together with a label and a description. The section employs three types of measure. Aggregates (`agg`) report the total annual flow of wealth transfers of the household sector; monetary values are always shown in national currency, in nominal terms, with no adjustment for inflation. Where the national currency changed over the period covered by a series, the whole series is expressed in the currency currently in force: for euro-area countries, for instance, values referring to years before the changeover are reported in euros rather than in the legacy national currency, so that a series is expressed in a single unit over its entire length. Ratios (`rto`) express the same annual flow relative to national income, which is the standard way of assessing the macroeconomic importance of inheritance and the only form in which the series can be compared across countries and across centuries. Rates (`rat`) report the average effective tax rate applied to the flow.

Table 6.2: Inheritance Trends: Variable Type

Code	Label	Description
rat	Rate	In general, a rate is expressed as a percentage. For instance, the marginal inheritance tax rate is the amount of tax that is paid on an additional dollar of inheritance received. It represents the rate at which a person's tax liability increases as their inheritance increases. The concept can also be applied to the saving rate which refers to the percentage of disposable income that is saved or not spent on consumption.
rto	Ratio	A ratio describes the relationship between two quantities and is expressed as the quotient of one quantity divided by another. For example, if a country's total private net wealth is €10,000 billion and its total national income is €2,000 billion, the ratio of private wealth to national income is 5 to 1, as total private wealth is five times the amount of national income.
agg	Aggregate	Aggregate value for a given institutional sector. The value is reported without knowing whether transactions that occur between units within the same sector are eliminated or kept during the aggregation.

6.3.2 `Concept`

The fourth element of the `varcode` identifies the `Concept`. In the Inheritance Trends database, a concept is the object being measured: either the type of wealth transfer the flow estimate refers to, or the effective tax rate levied on that transfer. Table 6.3 reports the concepts and the corresponding identifiers used in the `varcode` of the Inheritance Trends database, together with a detailed description and the list of available `Variable Type` associated with each concept.

Two transfer concepts are distinguished. Inheritances (`etnwea`) cover wealth left at death only. Inheritances & Gifts (`etnweg`) cover wealth left at death together with inter vivos gifts and donations, and is the broader and more widely available of the two. Keeping them separate is essential: in countries where gifts are a common way of advancing a bequest, the two concepts can differ substantially, and a comparison across countries that mixed them would be misleading. Wherever a source allows it, we publish both, so that users can gauge the size of the gift component directly. The third concept, the average effective tax rate (`averat`), is defined as the ratio between official wealth-transfer tax revenue and the estimated total tax base, that is, total estate, inheritance, and gift (EIG) tax revenue divided by the total flow of inheritances and gifts in a given year. It therefore measures the share of the annual flow of wealth transfers that is actually collected in taxes, and it is not a statutory rate: it reflects jointly the tax schedule in force, the exemptions and reliefs granted, and the extent to which transfers are declared at all.

Table 6.3: Inheritance Trends: Concept Dictionary

Code	Label	Description	Var Type
etnweg	Inheritances & Gifts	Inheritances & Gifts refers to wealth left at death (bequests) and intervivos gifts and donations. The value refers to the value of all possessions, tangible and intangible assets left at death, and to the value of all assets donated in life.	agg, rto
etnwea	Inheritances	Inheritances refer to wealth left at death (bequests), namely the value of all possessions, tangible and intangible assets left at death.	agg, rto
averat	Average Effective Tax Rate	The average tax rate is computed as the ratio between official tax revenue and estimate total tax base (e.g. the average effective wealth transfers tax rate is computed as the total EIG tax revenue divided by the total flow of inheritances and gifts in a given year).	rat

6.3.3 `Section-Specific`

In the Inheritance Trends database, the section-specific part of the `varcode` refers to the type of estimate from which the flow of wealth transfers is derived. The database distinguishes two types: the fiscal flow (`ff`) and the economic flow (`ef`). The list of permitted strings and a short description is provided in Table 6.4.

This distinction is the central methodological divide of the section, and it is the reason why two estimates for the same country and year may legitimately differ. What separates the two is the *primary source* on which the estimate rests, not the amount of work the authors put into it: both are the outcome of a research exercise, and neither is a raw figure lifted from a statistical table.

The **fiscal flow** is built on fiscal data: the estates, inheritances, and gifts reported to the tax authority, as recorded in estate tax returns, inheritance tax statistics, and successions registers. These records are the starting point rather than the final estimate. Taken as they stand, they capture only the transfers that are declared, and their coverage moves with the tax legislation in force, which changes over time and across countries: estates below the filing threshold, assets that are exempt or benefit from special reliefs, and transfers that go unreported are absent from the raw returns. Authors therefore adjust the fiscal material before arriving at a flow estimate — grossing up for non-filing estates, imputing the value of tax-exempt assets and of asset classes outside the scope of the tax, correcting for valuation rules that depart from market values, and reconstructing series across legislative breaks. The specific adjustments differ from source to source.

The **economic flow** is instead built on an ensemble of macroeconomic and demographic data, chiefly national accounts, typically by combining aggregate household wealth with mortality rates and with the ratio between the average wealth of the deceased and the average wealth of the living. It aims at the full economic magnitude of the transfer, independently of what is declared for tax purposes, at the cost of relying on estimation assumptions that vary from source to source.

Neither measure dominates the other, and we publish both wherever they are available. The fiscal flow stays closer to observed transfers and is the natural benchmark when the object of interest is the tax base; the economic flow is the appropriate measure when the object of interest is the intergenerational transmission of wealth as a whole.

The gap between the two is itself informative. As recalled by Piketty [59], who introduced the concept of an economic flow estimate of bequests, the difference between the economic flow and the fiscal flow is generally positive, and it can be read as an overall measure of tax evasion and avoidance: it captures the transfers that escape the fiscal records altogether, together with the undervaluation of those that are

Table 6.4: Inheritance Trends: Section-Specific

Code	Label	Description
ef	Economic Flow	Estimates from national accounts
ff	Fiscal Flow	Estimates from fiscal records

declared. What is striking, however, is how small that gap usually turns out to be. The two approaches rest on entirely independent bodies of data and on entirely different estimation methods, yet in practice they deliver surprisingly close estimates. This convergence is one of the reasons to have some confidence in both series, and it is also why the two can be read alongside one another rather than as competing measures.

For the same reason, users should not compare a fiscal flow for one country with an economic flow for another without an assessment of the different nature of the two methods and of the data they rely on.

6.4 The `percentile` variable in the Inheritance Trends Section

In addition to the `varcode`, values are indexed by the `percentile` variable, which identifies the segment of the population an estimate refers to. The Inheritance Trends section is not a distributional section: every series published here refers to the reference population as a whole, and the `percentile` variable therefore takes the single value *p0p100* throughout, as reported in Table 6.5. The variable is retained so that each estimate is fully identified by the same set of keys, and so that the population an estimate refers to is stated explicitly rather than left implicit. Extending the section with estimates of wealth transfers received by different segments of the distribution is an important direction for future releases of the GC Wealth Project.

Table 6.5: Inheritance Trends: Percentiles

Code	Label	Description
p0p100	Overall Population	Everyone in the reference population

6.5 Construction of the Inheritance Trends Section

The procedure used to construct the Inheritance Trends database proceeds in three steps. First, we identify the relevant sources and obtain the raw data. Second, we transform and harmonize the raw data to fit our standards in terms of format and structure. Third, we run a set of tests and append the source-specific estimates to the database.

6.5.1 Step 1: Identification and Classification of Sources

The starting point is the identification of relevant estimates of the annual flow of wealth transfers. In principle, the range of source *types* that could supply such estimates is wide, and would include official statistics produced by national or cross-national institutions, government and corporate research, and survey data, alongside academic research.

In practice, however, the sources of the Inheritance Trends section are exclusively academic research. There is no official statistic, national or cross-national, that publishes the annual flow of inheritances and gifts as such: the underlying fiscal records and national accounts exist, but the step from those records to a flow estimate is a research exercise, and it is performed in academic work. Each source is therefore a study, or a set of companion studies, that reconstructs the flow for one country over a long historical period, or, in the case of the cross-national source, for many countries over a shorter recent period.

Table 6.6 lists the sources currently included in the Inheritance Trends database, together with their country coverage, the period they span, and the `varcode` components they provide. The strong asymmetry visible in the table is a substantive feature of the field rather than an artifact of our selection: long historical series exist only for the small number of countries whose estate and inheritance tax records have been systematically exploited, whereas broad country coverage is available only for recent decades.

Table 6.6: Inheritance Trends: Sources and Coverage

Legend	Source	Countries	Period	Concepts	Flow	Obs.
Guzzardi and Morelli (2026)	Guzzardi2026	63	1995-2024	averat, etnweg	ef	4842
Acciari and Morelli (2022)	Acciari2021	1	1995-2016	etnwea, etnweg	ff	88
Alvaredo et al. (2017)	Alvaredo2017	1	1870-2013	etnweg	ef	144
Apostel (2025)	Apostel2025	1	2009-2022	etnwea, etnweg	ff	24
Atkinson (2018)	Atkinson2012	1	1896-2008	etnwea, etnweg	ff	404
Brülhart et al. (2018)	Brulhart2018	1	1911-2011	etnweg	ef	9
Brülhart et al. (2026)	Brulhart2026	1	2002-2021	etnwea, etnweg	ff	40
Gabbuti and Morelli (2025)	Gabbuti2025	1	1864-2016	etnweg	ff	65
Piketty (2011)	Piketty2011	1	1826-2008	etnwea, etnweg	ef, ff	848
Schinke (2012)	Schinke2012	1	1911-2009	etnweg	ef	7

Once the relevant source is identified and correctly classified, we acquire the raw data. For the Inheritance Trends section we do not produce our own estimates from micro data: the published estimates are used as they are made available by the authors, whether in the article itself, in its appendix, or in the replication material accompanying it. Where the authors publish several variants of the same series, we retain a single one, as described in Step 2.

Note that the country coverage of this section rests overwhelmingly on a single source. Of the 63 countries covered, 63 come from the new research by Guzzardi and Morelli [42], which alone accounts for roughly 75% of all observations in the section and spans the period 1995-2024. All the remaining sources together cover 7 countries, so that 56 of the 63 countries in the section are available thanks to the work by Guzzardi and Morelli [42]. Before it, cross-national evidence on the magnitude of inheritance flows was essentially limited to a handful of Western European countries and the United States.

All other sources therefore can be read as adding depth. For the few countries they cover, they reach far back in time — in some cases to the early nineteenth century, well beyond the recent decades covered by the cross-national estimates — and they supply the fiscal flow variant of the transfer series. The two groups of sources are thus complementary: one establishes how large wealth transfers are across a broad set of countries today, the others establish how that magnitude has evolved over the very long run in the countries whose

fiscal records allow it.

Note also that alongside the country-level estimates, Guzzardi and Morelli [42] also report regional aggregations, which pool countries into broader geographical groupings. In this version of the dataset we retain only the country estimates they provide in the paper. The regional aggregates are not published in this dataset, and users interested in them should refer to the original paper.

6.5.2 Step 2: Transformation and Harmonization of Raw Data

The published raw data may come in various shapes or formats, including .pdf documents, and .xlsx or .csv files. Therefore, we need to process this information and harmonize the source-specific series to conform to our formatting standards. This involves assigning each data point (`value`) with relevant information, including its data source (`source`), reference year (`year`), country code (`GEO`, `GEO_long`), type of measure (`varcode`), and the reference population (`percentile`, always *p0p100* in this section). This procedure ensures a consistent data structure across all sources.

Two harmonization choices deserve to be made explicit. First, a source may publish the flow of wealth transfers either as an aggregate in national currency or as a ratio to national income, and often only one of the two. We do not convert one into the other, because doing so would require adopting a national income denominator that may differ from the one used by the authors; we publish what the source publishes. This is why the availability of `agg` and `rto` varies across sources in Table 6.6. Second, monetary aggregates are always reported in national currency and in nominal terms, with no adjustment for inflation. Where a series spans a change of currency — a redenomination, or the adoption of the euro — the values referring to the earlier period are converted, so that the series is expressed in the currency currently in force over its entire length and contains no unit break. A long `agg` series is therefore internally consistent, but it remains a nominal series: it is not comparable across countries without conversion, and its growth over a long historical period reflects price dynamics as much as the growth of the transferred wealth itself. For long-run and cross-country comparisons, the ratio to national income (`rto`) is therefore the appropriate measure; alternatively, the supplementary variables can be used to adjust the aggregates for price and exchange rate dynamics.

It is also important to note that when a source provides multiple estimates for the same series, reflecting alternative assumptions about mortality differentials, the treatment of gifts, or the valuation of assets, we select only one of these values, typically the benchmark estimate as defined in the underlying research.

Finally, where a country is covered by more than one source, we do not merge or splice the resulting series into a single time series. Different sources rest on different records and different estimation choices, and a

spliced series would conceal a methodological break rather than resolve it. The series are published side by side under their respective `source` identifiers, so that the choice between them remains explicit and is left to the user.

6.5.3 Step 3: Testing and Appending

After making sure the acquired estimates follow our formatting standards, we run a set of consistency checks and tests before we append them to the Inheritance Trends database. Besides the general formatting and duplication checks, these include substantive tests: that the ratio to national income lies in a plausible range and that its aggregate counterpart, where both are available, is consistent with it; that the flow of inheritances and gifts (`etnweg`) is not smaller than the flow of inheritances alone (`etnwea`) for the same country, year, source, and flow type; and that the average effective tax rate (`averat`) lies between zero and one and is consistent with the tax revenue and the flow of transfers from which it is derived.

6.6 Additional Information on the Inheritance Trends Section

For additional information about the Inheritance Trends section, we refer the reader to the Appendix of this Documentation, where we provide a list of all sources included in the Inheritance Trends database, country-specific information on the coverage of the database, and additional information on the precise treatment of selected sources (Section E).

Appendix A

Supplementary Variables

Table A.1: Variables from wid.world

Variable	Short Name	Simple descrpition (original)
inyixx	National income price index	Price index that reflects the evolution of the price level for all new, domestically produced, final goods and services in the economy.
mgdpro	Gross domestic product	Gross domestic product is the total value of goods and services produced by the national economy.The national economy - in the national accounts sense - includes all domestic sectors, i.e. all entities that are resident of a given country (in the sense of their economic activity), whether they belong to the private sector, the corporate sector, the governement sector.
mnninc	National income	National income aims to measure the total income available to the residents of a given country. It is equal to the gross domestic product (the total value of goods and services produced on the territory of a given country during a given year), minus fixed capital used in production processes (e.g. replacement of obsolete machines or maintenance of roads) plus the net foreign income earned by residents in the rest of the world.

mpweal	Net private wealth	Net private wealth is the total value of non-financial and financial assets (housing, land, deposits, bonds, equities of corporations, etc.) held by private owners (households and foundations), minus their debts. The private sector - in the national accounts sense - includes the personal sector (households) and the non-profit sector (foundations, religious organizations, etc.). In certain countries, availables sources do not allow to decompose the wealth owned by each of these two sub-sectors, and we only provide total net private wealth.
nomgdp	Nominal GDP	Nominal GDP adjusted using the national income price index.
nomnni	Nominal national income	Nominal national income adjusted using the national income price index.
npopem	Employed population	Number of employed individuals.
npopul	Population	Number of individuals.
ntaxma	Number of tax units - married couples & single adults	Number of married couples and single adults as tax units.
xlceup	PPP conversion factor, LCU per EUR	PPP conversion factor of current local currency to current PPP EUR.
xlceux	Market exchange rate, LCU per EUR	Official exchange rate of the local currency to EUR.
xlcusp	PPP conversion factor, LCU per USD	PPP conversion factor of current local currency to current PPP USD.
xlcusx	Market exchange rate, LCU per USD	Official exchange rate of the local currency to USD.
xlcyup	PPP conversion factor, LCU per CNY	PPP conversion factor of current local currency to current PPP CNY.
xlcyux	Market exchange rate, LCU per CNY	Official exchange rate of the local currency to CNY.

Appendix B

Appendix to the Wealth Topography Section

B.1 Introduction

The Appendix of the Wealth Topography section of the GC Wealth Project provides additional information on the concepts included in the Wealth Topography and detailed source-specific documentation. In particular, this appendix provides:

- the full list of sources included in the Wealth Topography (Section B.2),
- the full conceptual grid used in the GC Wealth Project (Section B.3),
- source-specific detailed information on raw data source, all source-specific composition tables reporting all composition rules used to obtain the wealth concepts, and additional tables on conceptual and manual mapping (Section B.4).

B.2 Sources Included in the Wealth Topography Section

All data sources included in the current version of the Wealth Topography database are reported in Table B.1. In addition to the source name and bibliographic reference, the table reports the source type and the consultation date ("Download date"). All sources included in the Wealth Topography database can be distinguished according to types of national accounts:

- Balance Sheets contain holdings of non-financial assets (e.g., real estate assets or machinery), financial assets (e.g., deposits or equities), and liabilities (e.g., home mortgages) at a point in time.
- Financial Accounts contain holdings of financial assets (e.g., deposits or equities), and liabilities (e.g., home mortgages) at a point in time.

In other words, in the Wealth Topography databse, Financial Accounts are financial balance sheets in which only holdings of financial assets and liabilities are reported. In both cases, we report stocks or outstanding levels, i.e., holdings of assets and liabilities at the end of each accounting period (year). Outstanding levels reflect changes in transactions, nominal holding gains/losses, and other changes occurred throughout the year.

Table B.1: Sources in the Wealth Topography

B.3 Full Conceptual Grid

Once raw data have been obtained and classified, we harmonize them using the Wealth Topography Conceptual Grid, a table that assigns an alphanumeric identifier to each item or instrument of the balance sheet. The full grid is reported in Table B.2. Under the column `Code`, we report the code that identifies each item of the balance sheet (e.g., `AN111` stands for `Dwellings`). The code consists of two elements (letters and numbers), and, in the case of financial assets and liabilities, it also contains a special character. The alphabetic part of the code identifies whether a specific balance sheet component falls in the category of non-financial assets (`AN`), financial assets (`A_AF`) or liabilities (`L_AF`). The numeric part of the code identifies the class of assets and liabilities to which the instrument belongs.

Table B.2: Full GC Wealth Topography Conceptual Grid

na_code	Description	Financial position
AN	Produced and non-produced non-financial assets	ga
AN1	Produced non-financial assets	ga
AN11	Fixed assets by type of assets	ga
AN111	Dwellings	ga
AN112	Other buildings and structures	ga

B.4 Source-Specific Documentation

This section provides source-specific detailed information on raw data source, all source-specific composition rules used to obtain the macro-categories of the Wealth Topography (`concept`), and additional tables on mapping. We recall that raw data sources included in the Wealth Topography database can be classified in three macro groups:

1. Raw data sources published by central banks and national statistical institutes that use the

SNA2008/ESA2010 framework to organize and disseminate the data. We refer to this raw data sources simply as cross-national official statistics.

2. Raw data sources published by central banks and national statistical institutes that use variants of the SNA2008/ESA2010 framework or other frameworks to organize and disseminate the data. We refer to these raw data sources as cross-national official statistics that use variants of SNA2008/ESA2010 framework.

3. Raw data sources contained in surveys and academic papers or published by central banks and research institutes that use frameworks different from the SNA2008/ESA2010 framework to organize and disseminate the data. We refer to these data sources as cross-national official survey data or cross-national academic research that do not use the SNA2008/ESA2010 framework.

When formulating the composition rules, we construct rules that can be applied to all years during which all sub-components of each concept can be observed. This formulation of composition rules allows us to preserve time consistency in the construction of concepts.

B.4.1 Bank of Italy - Financial Accounts (`BoI_FA`)

The Bank of Italy provides financial balance sheets of the Households and NPISH sector as parts of its quarterly financial accounts publication, so-called *Conti Finanziari* Bank of Italy [15]. While raw data are published at quarterly frequency, we use the end-of-year observation. This raw data source is classified as cross-national official statistics, and its mapping is automatic since the Bank of Italy organizes and disseminates raw data according to the SNA2008/ESA2010 guidelines. Table B.3 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

B.4.2 Bank of Italy & ISTAT - Balance Sheet (`BoI_NA`)

The source Bank of Italy & ISTAT - Balance Sheet (`BoI_NA`) is based on the joint Bank of Italy and ISTAT estimates of wealth published as "The Wealth of Italy's Institutional Sectors" Bank of Italy and Istat [16]. This publication provides annual estimates of net wealth, assets, and liabilities of households and other institutional sectors, together with a cross-country comparison on the evolution of balance sheets. This raw data source is classified as cross-national official statistics, and its mapping is automatic since the Bank of Italy organizes and disseminates raw data according to the SNA2008/ESA2010 guidelines. Table B.4 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table,

the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this source, we obtain "Net Wealth" (`netwea`) as the sum of "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) and "Housing & Land" (`nfahou`), net of "Debt" (`fliabi`).

B.4.3 European Central Bank Non-EU - Financial Accounts (`ECB_IDCSA`)

The European Central Bank provides estimates of financial balance sheet for non-EU countries on its Statistical Data Warehouse. These data are included in the source European Central Bank Non-EU (`ECB_IDCSA`), which corresponds to the IDCS - Sector accounts in the International Data Cooperation Task Force Context Unknown [84]. The underlying database collects financial accounts (both flows and levels) for each institutional sector as publishes by Eurostat, OECD, and the United Nations. Data are originally published at both quarterly and annual frequency. This raw data source is classified as cross-national official statistics for which mapping is automatic since the European Central Bank organizes and disseminates raw data according to the SNA2008/ESA2010 guidelines. Table B.5 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

B.4.4 European Central Bank EU - Financial Accounts (`ECB_QSA`)

The source European Central Bank EU (`ECB_QSA`) corresponds to the Quarterly Sector Accounts published by the European Central Bank on the Statistical Data Warehouse Unknown [83]. The Quarterly Sector Accounts provide quarterly estimates of outstanding levels of financial assets and liabilities for the European Union (EU) countries, together with a detailed breakdown of institutional sectors and financial instruments. The original frequency of data is quarterly but we retain the end-year observation. This raw data source is classified as cross-national official statistics, and its mapping is automatic since the European Central Bank organizes and disseminates raw data according to the SNA2008/ESA2010 guidelines. Table B.6 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

B.4.5 European Central Bank EU Distributional Wealth Accounts - Balance Sheet (`ECB_DWA_topo`)

The source European Central Bank EU Distributional Accounts (`ECB_DWA_topo`) are experimental statistics produced by the European System of Central Banks (ESCB). The complement macroeconomic sector ac-

counts with distributional information for the household sector. The DWA links European Central Bank EU (`ECB_QSA`) data with Household Finance and Consumption Survey - Balance Sheet (`HFCS_topo`) with a view to providing an assessment of the distribution of household wealth that is consistent with the aggregates compiled in the sector accounts. This raw data source is classified as cross-national official statistics, and its mapping is automatic since the European Central Bank organizes and disseminates raw data according to the SNA2008/ESA2010 guidelines. Table B.7 provides an overview of the general and source-specific composition rules used to compute the concepts. Housing wealth in the original source is provided in net values, therefore, we add housing loans to compile the gross aggregate.

B.4.6 Eurostat - Financial Accounts (`Est`)

The data source Eurostat - Financial Accounts (`Est`) corresponds to the Financial Flows and Stocks publication of Eurostat, the statistical office of the European Union Unknown [85]. This data source reports financial assets held and the liabilities outstanding at the end of each year, for each institutional sector of the economy, according to the SNA2008/ESA2010 framework. This is a cross-national official statistics source type, and its mapping is automatic. Table **??** provides an overview of the source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the correspondent composition rule is used.

B.4.7 Federal Reserve Board B.101 - Balance Sheet (`FED_B101`)

The source Federal Reserve Board B.101 - Balance Sheet (`FED_B101`) corresponds to the table B.101: Balance Sheet of Households and Nonprofit Organizations published by the Federal Reserve Board in the Z.1 Financial Accounts of the United States Board of Governors of the Federal Reserve System [20]. The table covers the entire balance sheet of the households and nonprofit organizations sector. Relative to the mapping procedure, this raw data source is classified as cross-national official statistics that use variants of SNA2008/ESA2010 framework. Hence, we manually map each item from the raw data source into an item of the grid (see Table B.10 for the manual mapping). Table B.9 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this source, we obtain "Net Wealth" (`netwea`) as the sum of "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) and "Housing & Land" (`nfahou`), net of "Debt" (`fliabi`).

B.4.8 Federal Reserve Board B.101.H - Balance Sheet (`FED_B101h`)

The source Federal Reserve Board B.101.H - Balance Sheet (`FED_B101h`) corresponds to the table B.101.h: Balance Sheet of Households published by the Federal Reserve Board as supplementary table in the Z.1 Financial Accounts of the United States Board of Governors of the Federal Reserve System [20]. The table covers the entire balance sheet of the households and is obtained as a residual - that is by subtracting assets and liabilities of the nonprofit sector from the combined balance sheet of households and nonprofit organizations sector (table B.101). This raw data source is classified as cross-national official statistics that use variants of the SNA2008/ESA2010 framework, and we manually map each item from the raw data source into an item of the grid (see Table B.12 for the manual mapping). Table B.11 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this source, we obtain "Net Wealth" (`netwea`) as the sum of "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) and "Housing & Land" (`nfahou`), net of "Debt" (`fliabi`).

B.4.9 Federal Reserve Board B.101.N - Balance Sheet (`FED_B101n`)

The source Federal Reserve Board B.101.N - Balance Sheet (`FED_B101n`) corresponds to the table B.101.n: Balance Sheet of Nonprofit Organizations published by the Federal Reserve Board as supplementary table in the Z.1 Financial Accounts of the United States Board of Governors of the Federal Reserve System [20]. The table covers the entire balance sheet of the nonprofit organizations sectors. This raw data source is classified as cross-national official statistics that use variants of the SNA2008/ESA2010 framework, and we manually map each item from the raw data source into an item of the grid (see Table B.14 for the manual mapping). Table B.13 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this source, we obtain "Net Wealth" (`netwea`) as the sum of "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) and "Housing & Land" (`nfahou`), net of "Debt" (`fliabi`).

B.4.10 Federal Reserve Board S.3.a (IMA) - Balance Sheet (`FED_S3a_IMA`)

The source Federal Reserve Board S.3.a (IMA) - Balance Sheet (`FED_S3a_IMA`) corresponds to the table S.3.a: Households and Nonprofit Institutions Serving Households published by the Federal Reserve Board in the Integrated Macroeconomic Accounts section of the Z.1 Financial Accounts of the United States Board of Governors of the Federal Reserve System [20]. The table covers the entire balance sheet of the households

and nonprofit organizations sector but the underlying data source is different from that used to obtain table B.101. In fact, the Integrated Macroeconomic Accounts combine production, income and saving, and capital formation from the National Income and Product Accounts (NIPA) and financial transactions and asset revaluations from the Financial Accounts with changes in net wealth from the balance sheet (table B.101). This raw data source is classified as cross-national official statistics that use variants of the SNA2008/ESA2010 framework, and we manually map each item from the raw data source into an item of the grid (see Table B.15 for the manual mapping). Table B.15 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this source, we obtain "Net Wealth" (`netwea`) as the sum of "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) and "Housing & Land" (`nfahou`), net of "Debt" (`fliabi`).

B.4.11 OECD - Financial Accounts (`OECD_FA`)

The source OECD - Financial Accounts (`OECD_FA`) corresponds to the OECD's table Households' Financial Assets and Liabilities (QASA_7HH table) which provides a detailed breakdown of households' loans, investment funds shares, life insurance and annuity entitlements, and pension entitlements OECD [56]. This raw data source assembles various sources from central banks and national statistical institutes. This raw data source is classified as cross-national official statistics, and its mapping is automatic since the OECD organizes and disseminates data according to the SNA2008/ESA2010 framework. Table B.18 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

B.4.12 OECD - Nonfinancial Accounts (`OECD_NA`)

The source OECD - Financial Accounts (`OECD_NA`) corresponds to the OECD's table Annual balance sheets for non-financial assets (SNA_TABLE9B table) which provides a detailed breakdown of produced and non-produced non-financial assets for different institutional sectors, including the household sector OECD [55]. This raw data source is classified as cross-national official statistics, and its mapping is automatic since the OECD organizes and disseminates data according to the SNA2008/ESA2010 framework. Table B.17 provides an overview of the general and source-specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

B.4.13 Luxembourg Wealth Study Database - Balance Sheet (`LWS_topo`)

The source Luxembourg Wealth Study Database - Balance Sheet (`LWS_topo`) is the Luxembourg Wealth Study Database which provides cross-national harmonized micro-data (household- and individual-level data) on assets, liabilities, and net wealth LIS [53]. Aggregate concepts are obtained multiplying household-level micro-data by the population weight and they are the average across five implicates (Rubin's Rule). The organization of assets and liabilities in the Luxembourg Wealth Study Database is not directly comparable to the GC Wealth Project conceptual grid. Therefore, this raw data source is classified as cross-national academic research that do not use the SNA2008/ESA2010 framework for which we introduce a source-specific conceptual grid (see Table B.20) and composition table (see Table B.19). In the composition table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this specific source, "Net Wealth" (`netwea`) is obtained ex-post, that is by combining the available concepts of the Wealth Topography. More specifically, "Net Wealth" is computed as "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) plus "Housing & Land" (`nfahou`) minus "Debt" (`fliabi`). Deposits are constructed from the variable Deposit Accounts And Cash (`hafc`). In countries where this variable includes cash according to the original survey, the GC wealth Project's data warehouse does not report the concept "Deposits" based on the LWS.

B.4.14 Household Finance and Consumption Survey - Balance Sheet (`HFCS_topo`)

The source Household Finance and Consumption Survey - Balance Sheet (`HFCS_topo`) corresponds to the Household Finance and Consumption Survey (HFCS), a collection of harmonized micro-data on households' balance sheets and consumption Household Finance and Consumption Network [43]. The HFCS is housed at the European Central Bank but the survey is conducted nationally, mostly by central banks. To obtain aggregate concepts from household-level data, we used household-level weights. Moreover, aggregate data reported in the Wealth Topography are an average across all five implicates (Rubin's Rule). The organization of assets and liabilities in the Household Finance and Consumption Survey is not directly comparable to the GC Wealth Project conceptual grid. Therefore, this raw data source is classified as cross-national official survey data that do not use the SNA2008/ESA2010 framework, and we introduce a source-specific conceptual grid (see Table B.22) and composition table (see Table B.21). In the composition table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

B.4.15 World Inequality Database - Balance Sheet (WID_topo)

The source World Inequality Database - Balance Sheet (WID_topo) corresponds to the World Inequality Database (WID) World Inequality Database [94]. The concepts included in the Wealth Topography database are the WID aggregate wealth variables, converted in nominal values using the country-specific price deflator provided by WID. Among the WID estimates, we have included in the Wealth Topography database only countries with wealth data available for at least two asset group. Thus, our databse excludes those estimates of wealth aggregates that are heavily imputed with data available only for one asset group or for few asset sub-components. The organization of assets and liabilities in the World Inequality Database - Balance Sheet is not directly comparable to the GC Wealth Project conceptual grid. Therefore, this raw data source is classified as cross-national academic research that does not use the SNA2008/ESA2010 framework, and we introduce a source-specific conceptual grid (see Table B.24) and composition table (see Table B.24). In the composition table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this source, "Net Wealth" (`netwea`) may be different from the sum of "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) and "Housing & Land" (`nfahou`), net of "Debt" (`fliabi`) because of discrepancies present in the raw data source.

B.4.16 Atlas of the Offshore World - Financial Accounts (AOW)

The source Atlas of the Offshore World (AOW) is based on a research project by the EU Tax Observatory and Skatteforsk - Centre for Tax Research to inform the global debate around international tax evasion and avoidance. It offers up-to-date information about the dynamic of profit shifting by multinational companies and offshore wealth. Household offshore financial wealth refers to financial assets held by individuals outside of their residence country. To obtain offshore financial wealth, researchers exploit official statistics published by the Swiss central bank, the Bank for International Settlements, and systematic anomalies in the international investment positions of countries. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. As the information on offshore real estate is currently available for one year only, we do not include in the current version of the topography section.

B.4.17 European Commission Taxation Papers - Financial Accounts (ECOW)

The data source European Commission Taxation Papers (ECOW) corresponds to a research projected by Charles Vellutini, Georges Casamatta, Léa Bousquet, and Grzegorz Poniatowski. Household offshore financial wealth refers to financial assets held by individuals outside of their residence country. To obtain offshore financial

wealth, researchers exploit systematic anomalies in the international investment positions of countries. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

B.4.18 Credit Suisse Global Wealth Report - Balance Sheet (`CS_topo`)

The Credit Suisse Global Wealth Report (`CS_topo`) provides wealth estimates for various countries in the the period from 2000 to 2022 based on household balance sheets and surveys. We include a time series on aggreagte wealth information if the data quality is defined as fair or better, which results in a set of 51 countries. The data is primarily derived from national surveys and administrative records, with adjustments made to account for the upper tail of the wealth distribution using rich list data, such as Forbes' The World's Billionaires list. The organization of assets and liabilities in the Credit Suisse Global Wealth Report is not directly comparable to the GC Wealth Project conceptual grid. Therefore, this raw data source is classified as cross-national academic research that do not use the SNA2008/ESA2010 framework, and we introduce a source-specific conceptual grid (see Table B.20) and composition table (see Table B.19). In the composition table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used. For this specific source, "Net Wealth" (`netwea`) is obtained ex-post, that is by combining the available concepts of the Wealth Topography. More specifically, "Net Wealth" is computed as "Financial Assets & Fixed Capital of Personal Businesses" (`nnhass`) plus "Housing & Land" (`nfahou`) minus "Debt" (`fliabi`). We thank Prof. Anthony Shorrocks for providing the dataset for the GC Wealth Project.

B.4.19 Statistics Canada Distributional Wealth Accounts - Balance Sheet (`StatCan_DWA_topo`)

The data source Statistics Canada Distributional Wealth Accounts (`StatCan_DWA_topo`) corresponds to Statistics Canada's table Distributions of household economic accounts, wealth, by characteristic, Canada, quarterly **StatCan2025**. It provides information on household's assets and liabilities, and offers breakdowns for different groups of households, including households that differ in their rank in the wealth distribution. For the Wealth Topography Section of the GC Wealth data warehouse, we select "All households". The data comes in quarterly format. The original frequency of data is quarterly but we retain the end-year observation. This raw data source is classified as cross-national official statistics that use variants of the SNA2008/ESA2010 framework, and we manually map each item from the raw data source into an item of the grid (see Table B.30 for the manual mapping). Table B.29 provides an overview of the general and source-

specific composition rules used to compute the concepts. In the table, the column "Frequency" reports the number of source-sector-concept triples for which the corresponding composition rule is used.

Table B.3: Composition rules: Bank of Italy - Financial Accounts

Sector	Code	Concept	Composition rule using codes	Frequency
Households & NPISH	facdbl	Cash, Deposits, Bonds & Loans	(A_AF2BI2) + (A_AF29) + (A_AF31) + (A_AF32) + (A_AF41)	1
Households & NPISH	faeqfd	Stocks, Business Equities & Fund Shares	(A_AF51) + (A_AF52)	1
Households & NPISH	falipe	Pensions & Life Insurance	(A_AF6)	1
Households & NPISH	fliabi	Debt	(L_AF41) + (L_AF42) + (L_AF6)	1
Households & NPISH	nnhass	Financial Assets & Fixed Capital of Personal Businesses	(A_AF)	1

Table B.4: Composition rules: Bank of Italy and ISTAT - Balance Sheet

Sector	Code	Concept	Composition rule using codes	Frequency
Households & NPISH	facdbl	Cash, Deposits, Bonds & Loans	(A_AF2) + (A_AF3) + (A_AF4)	1
Households & NPISH	faeqfd	Stocks, Business Equities & Fund Shares	(A_AF51) + (A_AF52)	1
Households & NPISH	falipe	Pensions & Life Insurance	(A_AF6)	1
Households & NPISH	fliabi	Debt	(L_AF3) + (L_AF4) + (L_AF51) + (L_AF52) + (L_AF6) + (L_AF8)	1
Households & NPISH	netwea	Net Wealth	(Financial Assets & Fixed Capital of Personal Businesses) + (Housing & Land) - (Debt)	1
Households & NPISH	nfabus	Fixed Capital of Personal Businesses	(AN113) + (AN115) + (AN117) + (AN12)	1
Households & NPISH	nfadur	Durable Goods	(XDHHCE)	1
Households & NPISH	nfahou	Housing & Land	(AN111) + (AN1121) + (AN1122) + (AN1123) + (AN2112)	1
Households & NPISH	nfalan	Land	(AN2112)	1

Households & NPISH	nfhous	Housing	(AN111) + (AN1121) + (AN1122) + (AN1123)	1
Households & NPISH	nnhass	Financial Assets & Fixed Capital of Personal Businesses	(AN113) + (AN115) + (AN117) + (AN12) + (A_AF)	1

Table B.5: Composition rules: European Central Bank Non-EU - Financial Accounts

Sector	Code	Concept	Composition rule using codes	Frequency
Households	facdbl	Cash, Deposits, Bonds & Loans	(A_AF2) + (A_AF3) + (A_AF4)	13
Households	fadepo	Deposits	(A_AF22) + (A_AF29)	11
Households	faeqfd	Stocks, Business Equities & Fund Shares	(A_AF5)	13
Households	falipe	Pensions & Life Insurance	(A_AF6)	13
Households	fliabi	Debt	(L_AF3) + (L_AF4)	2
Households	fliabi	Debt	(L_AF3) + (L_AF4) + (L_AF5) + (L_AF6)	8
Households	fliabi	Debt	(L_AF4)	2
Households	fliabi	Debt	(L_AF4) + (L_AF5)	1
Households	nnhass	Financial Assets & Fixed Capital of Personal Businesses	(A_AF)	13
Households & NPISH	facdbl	Cash, Deposits, Bonds & Loans	(A_AF2) + (A_AF3) + (A_AF4)	20
Households & NPISH	fadepo	Deposits	(A_AF22) + (A_AF29)	15
Households & NPISH	faeqfd	Stocks, Business Equities & Fund Shares	(A_AF5)	20
Households & NPISH	falipe	Pensions & Life Insurance	(A_AF6)	20

Households & NPISH	fliabi	Debt	(L_AF3) + (L_AF4)	2
Households & NPISH	fliabi	Debt	(L_AF3) + (L_AF4) + (L_AF5)	2
Households & NPISH	fliabi	Debt	(L_AF3) + (L_AF4) + (L_AF5) + (L_AF6)	13

Appendix C

Appendix to the Wealth Inequality Section

C.1 Introduction

The Appendix to the Wealth Inequality section of the GC Wealth Project provides additional information on

- the full list of sources covered by the GC Wealth Project Wealth Inequality database in Section C.2
- source-specific documentation and information on the precise estimation method for own estimates (Demographic and Health Surveys, Harmonized Household Living Conditions Surveys, Household Finance and Consumption Survey, Living Standards Measurement Study, and Luxembourg Wealth Study Database),
- an explanation of the data inclusion criteria for sources that provide imputed wealth inequality estimates (Credit Suisse and the World Inequality Database) is available in Section C.3

C.2 Sources Included in the Wealth Inequality Section

All data sources included in the current version of the Wealth Inequality section are reported in Table C.1. For each source, the table provides the full citation (`Source`), the source type (`Source Type`), and the date of last consultation (`Date`). In the case of Demographic and Health Surveys, European Central Bank Distributional Wealth Accounts, FED Distributional Wealth Accounts, Global Findex Database, Living Standards Measurement Study, OECD Wealth Distribution Database, Statistics Norway, WAEMU Harmonized House-

hold Living Conditions Surveys, and World Inequality Database, `Date` indicates the date on which we have downloaded the data. In the case of microdata [43, 53], this column specifies the publication vintages as well as the date on which we have computed the estimates.

C.3 Source-Specific Documentation

For the Wealth Inequality database of the GC Wealth Project, the **Methodological Tables** provide a detailed documentation of each `source`, thus the primary source-specific documentation is provided in these tables. In this appendix, we summarize the most important aspects for two types of sources: *i)* sources for which we estimated measures of wealth inequality based on microdata [43, 53], and *ii)* sources where we could not cover the full range of estimates available in the raw data of source, especially because data points provided by the source are fully imputed [30, 94].

C.3.1 Household Finance and Consumption Survey (HFCS_ineq)

We have estimated wealth inequality using data waves one to four of the Household Finance and Consumption Survey [43]. As the HFCS is a mulitply imputed data set, we obtained all estimates by applying Rubin's Rule; that is, they are the mean of the estimates across the five implicates. Second, we have used the household level weights provided in the dataset for the estimations. Third, our net wealth estimates are based on the variable `dn3001`. This definition does not encompass private or occupational pension wealth, while private pension wealth is included even if it is not (directly) marketable (at the same value). Fourth, the HFCS is an ex ante harmonized survey; it is coordinated by the European Central Bank but conducted by the national central banks of the Eurosystem, and all countries survey, in principle, the same concept of net wealth. There are, however, important differences in the precise survey methodologies across countries and the resulting quality of the data, especially in terms of the coverage of the upper tail and the valuation of assets. Thus, while the survey is conceptually harmonized, the country-specific survey designs differ substantially. Some countries use (external) administrative data of different types to attach values to single components of net wealth, especially Finland, Estonia, Ireland, Latvia, and Lithuania. While sampling in most countries includes some type of oversampling of the upper tail, others do not even attempt to counterbalance the higher non-response rate at the top (Austria, Netherlands, Malta, and Slovenia). For the countries with over-sampling strategies, the precise procedure varies and is based on either individual, household, or region-specific estimates of wealth or wealth correlates. In the latest wave, the effective oversampling rates of the top 5 percent ranges from -28% (Czech Republic) to 345% (Spain) in the last wave of the survey, according to Household Finance and Consumption Network [43]. Finally, we work with an identical definition of net wealth across countries that excludes all private and occupational pension wealth. This cross-country harmonized definition might hide important aspects in country comparisons in light of (statutory) differences in the (relative) importance of the first, second, and third tier of pensions systems. The HFCS reports wealth only at the household level, and, at the moment, our database only covers estimates of wealth inequality referring to the distribution

among households.

C.3.2 Luxembourg Wealth Study (LWS_ineq)

The Luxembourg Wealth Study [53] provides cross-country harmonized microdata on household wealth and we employ waves Waves IV - XIII of the data. Except for one country, Norway, the underlying original data has been obtained via surveys. We have used household-level weights in the computation of the wealth inequality measures. Our preferred wealth definition is net wealth including private pension and life insurance plans (total real assets inclusive of consumer goods such as vehicles and other valuables, plus total financial assets, inclusive of long-term savings via life insurance and voluntary individual pensions plans, minus total liabilities; variable `anw`). We were able to implement this concept for the following countries: Austria, Canada, Chile, Estonia, Finland, France, Germany, Greece, India, Italy after 2004, Luxembourg, Mexico, Spain, Slovakia, Slovenia, the United Kingdom, and the United States. For other countries, certain types of assets and liabilities are not available via the Luxembourg Wealth Study. Given the absence of data, the net wealth concept for the following countries does not include private pension plans: Australia, Denmark, Italy up to 2002, Norway, South Korea, South Africa, and Sweden (variable `dnw`). We accessed the Luxembourg Wealth Study to estimate the wealth inequality measures on April 09, 2026.

C.3.3 Word Inequality Database (WID_ineq)

The World Inequality Database [94] provides estimates of wealth inequality for most countries of the world. Among these estimates, we have selected those that are consistent with our principle of not being fully imputed wealth inequality data. Our database thus includes estimates that are based on either survey or administrative data on the distribution of wealth for at least one single year. In the case of the World Inequality Database [94], this still implies a very generous coverage, as, for many European countries with time-series data published on the World Inequality Database [94], the number years for which micro data on the wealth distribution has been used is much smaller than the number of years for which the estimates derive from (backwards) extrapolation. Furthermore, wealth inequality estimates are available for multiple units of analysis, including equal-split adults (or households). As the set of estimates referring to equal-split adults is the most complete among the sources that qualify for our database, we have chosen these estimates, while not reporting statistics referring to other units of analysis. Table C.2 lists the countries covered by the GC Wealth Project Wealth Inequality database and, for each country (`Country`), the primary origin of the estimates as published by WID (`Original Source`) and the data type according to our classification (`Data Type`) which suggests substantial methodological heterogeneity underlying World Inequality Database [94]

estimates. We downloaded the data on February 09, 2026.

Table C.2: The selection of WID series available in the GC Wealth Project: notes on the primary source of data and their nature

Country	Original Source	Data Type
Austria	HFCS	Household survey and national accounts

United Kingdom	Alvaredo et al. (2018); Wealth and Assets Survey 2006 - 2018 as utilized in Blanchet & Martínez-Toledano (2023)	Inheritance/estate tax data, wealth survey and national accounts
United States	Saez & Zucman (2016, 2020b)	Capital income tax data, wealth survey, and national accounts
South Africa	Chatterjee et al. (2022)	Wealth tax/register data, other sources, and national accounts

C.3.4 Credit Suisse Global Wealth Report (CS_ineq)

Credit Suisse [30] provides estimates of household wealth holdings across 217 markets worldwide, with annual data available since 2000. The estimation process involves three main steps. In the first step, the aggregate level of wealth is established for each market. The preferred data source is household balance sheets (HBS) and/or financial balance sheets, which are currently available for 51 markets. For two additional markets, wealth levels are derived from household survey data. In markets lacking HBS or survey data, wealth estimates are imputed using cross-market regressions. In the second step, estimates of how wealth is distributed within each market are retrieved. Direct country-specific data on wealth distribution is available for only 40 markets. For all other markets, wealth distribution estimates are imputed based on income data. Finally, top-tail adjustments are made by relying on rich list data sources, which provide more accurate estimates of the wealth held by the ultra-wealthy.

Importantly, the GC Wealth Project Wealth Inequality Database only includes time series where estimates are based on direct country-specific data sources, excluding all markets where no micro-level information on wealth is available and estimates are imputed using cross-market regressions. As a result, the included time series cover only a subset of the markets analyzed in the 2023 report.

Table C.3 summarizes the data sources and reference years used for estimating the time series for the subset of 40 countries with information on wealth distribution that has been included in the GC Wealth Project. For each country, we specify the source of the per capita wealth estimate in the `Original Source: Aggregate` column, distinguishing between countries with both financial and non-financial balance sheet information (F and non-F) and those where household balance sheets contain only information on financial assets and debts (F). Reference years are summarized in the column `Reference Years: Macrodata`. The column `Original Source: Distribution` provides information about the microdata source used for estimating the inequality indicators (i.e., Gini index, wealth shares, and thresholds). The column `Reference Years: Microdata` reports the reference year. Data from the 2023 wave was kindly provided by Professor Anthony Shorrocks. Monetary estimates (average net wealth and percentile thresholds) were converted from dollars (the reference unit in the 2023 Report) using country-specific exchange rates provided by the CS research team.

Appendix D

Appendix to the Taxes on Wealth Section

D.1 Introduction

The Appendix of the Taxes on Wealth section of the GC Wealth Project provides additional information on the data creation and data validation processes and the full list of sources included.

D.2 Data Creation Process

Information on estate, inheritance, and gift taxes is collected from three broadly different source categories: 1) legal tax documents from public entities, 2) information on tax codes and schedules from third-party sources, and 3) tax revenue data from the OECD [58].

The construction of the database relies on a structured data pipeline that transforms heterogeneous, country-level tax schedule information into a harmonized and standardized warehouse. The process starts with manual data input from standardized Excel templates compiled for each source–country pair. To ensure comparability of Estate, Inheritance, and Gift tax schedules and rates across countries and over time, the information is stratified by transfer category (estate, inheritance, and gift) and donor relationship. Estate, Inheritance, and Gift tax information that does not fit into the harmonized set of variables is documented in country-year-specific Note. Table D.1 below reports the scheme for inputting tax information from each source for a country.

Table D.1: Legend: variable definitions and coding rules

Variable	Definition	Values	Meaning
GEO	2-digit Country ISO code	see sheet "Country codes"	In case of sub-national information for the U.S., use the federal 2-digit ISO code followed by a comma, a space, and the state-level code.
GEO_long	Name of the country	see sheet "Country codes"	In case of sub-national information for the U.S., use "United States" followed by a comma, a space, and the state name.
currency	3-digit Currency ISO code	see sheet "Currency"	The currency to be reported is the one used in the source.
AggSource	Category of source type	Cross-national official statistics	Cross-national data from official institutions, such as national accounts from central banks.
		Cross-national official survey data	Cross-national survey data from official institutions, such as household finance surveys from national statistical offices.
		Cross-national corporate research	Cross-national research published by corporate entities, such as private consultancy firms.
		Cross-national academic research	Cross-national research published by academic institutions, such as an academic journal article.
		Cross-national government research	Cross-national research published by government institutions, such as government-commissioned reports.
		Official statistics	Data from official institutions, such as national accounts from a country's central bank.
		Official survey data	Survey data from official institutions, such as household finance surveys from a country's national statistical office.
		Corporate research	Research published by corporate entities, such as private consultancy firms.

Table D.1: Legend: variable definitions and coding rules *(continued)*

Variable	Definition	Values	Meaning
		Academic research	Research published by academic institutions, such as an academic journal article.
		Government research	Research published by government institutions, such as government-commissioned reports.
		Government legislation	The actual text of public legislation.
		Government legislative info	Texts published by government institutions that provide descriptive information about public legislation, such as a government website explaining tax clauses.
		Government documents	Other texts published by government institutions, such as tax documents, forms, or descriptive reports.
Legend	Short explanation of the source (e.g. title of the document)		
Source	Short name of the source without spaces		
Link	Link to the source from website		
year_from	Year from which the input applies		Assuming that the information is valid for the year of introduction/reform/repeal independent of the month. The month of introduction/reform/repeal, if known, can be reported in the note.
year_to	Year up to which the input applies		Assuming that the information is valid for the year of introduction/reform/repeal independent of the month. The month of introduction/reform/repeal, if known, can be reported in the note.

Table D.1: Legend: variable definitions and coding rules *(continued)*

Variable	Definition	Values	Meaning
subnational_level	Whether the information applies to the national/federal level as opposed to the sub-nationa/regional/municipal level.	0	No
		1	Yes
applies_to	Group to which the tax applies. More than one category can be specified, separated by a comma.	children	The group consists of children of the donor/decedent. The group also includes grandchildren, parents and grandparents, unless otherwise stated in the note.
		spouse	The group consists of the spouse of the donor/decedent. The group includes the legal cohabitant unless otherwise specified in the note.
		siblings	The group consists of the siblings of the donor/decedent. The group also includes children of siblings, unless otherwise stated in the note.
		other relatives	The group consists of relatives of the donor/decedent, excluding spouse, children, and siblings.
		non relatives	The group consists of individuals who are not related to the donor/decedent.
		everybody	Every individual. This group is used also in case no EIG tax applies.
		unknown	We do not have information on the group to which the EIG tax applies, or on the specific assets on which the property and/or net wealth taxes are levied.

Table D.1: Legend: variable definitions and coding rules *(continued)*

Variable	Definition	Values	Meaning
tax	Name of the tax	inheritance	Tax on wealth transfers mortis causa (at the time of the donor's death) levied on the inheritances, i.e. on the amounts received by individual recipients. It may take into account the relationship of the individual recipients to the deceased.
		estate	Tax on wealth transfers mortis causa (at the time of the donor's death) levied on the estate value, i.e. on the total amount bequeathed.
		gift	Tax on gifts, i.e. wealth transfers inter vivos (when the donor is alive). It may take into account the relationship of the individual recipients to the donor.
status	Whether or not the country levies the specified tax for the given year. It is encoded as a 0/1 indicator variable.	0	No
		1	Yes
different_tax	Indicator for the estates, inheritances or gifts to be taxed through a non-EIG tax (e.g. personal income tax, capital income tax, real estate transfer tax). The tax, if known, can be specified in the Note.	0	No
		1	Yes
type_tax	The structure of the tax schedule, depending on the number of different positive marginal rates in the tax schedule.	1	Lump-sum (fixed)

Table D.1: Legend: variable definitions and coding rules *(continued)*

Variable	Definition	Values	Meaning
		2	Flat (proportional with a single rate applies to all tax base)
		3	Progressive by class (proportional with tax rates increasing with the tax base)
		4	Progressive by brackets (proportional with tax rates increasing with the tax base, with different portions of the tax base - brackets - taxed at different rates)
first_year	The first year the specified tax is introduced in the country. In case the tax was introduced before the year of legal birth of the country (such as in the case of unified kingdoms or of former colonies), it is set at the years of birth of the country with details in the Note.		
exemption	The exemption threshold in local currency units applicable to the sector, assuming no additional exemptions, credits or relief apply.	0	No exemption
		Positive number	Amount of the exemption
		_na	Not applicable because the tax is not levied
		_and_over	Full exemption (no tax is due)
schedule_lower_bounds	List, separated by a comma, of the values of tax base over which the tax rate applies in each bracket.	Non-negative number	The first lower bound needs to be a zero: adjust the schedule accordingly

Table D.1: Legend: variable definitions and coding rules *(continued)*

Variable	Definition	Values	Meaning
schedule_upper_bounds	List, separated by a comma, of the highest tax base values for which the tax rate applies in each bracket.	Positive number	
		_and_over	For the last upper bound, if open
marginal_rate	List, separated by a comma, of rates of taxation on tax base values between the bracket lower bound and the bracket upper bound.	0	No tax, full exemption or exemption bracket
		Positive number 0-100	
top_rate	The marginal tax rate that applies to the last bracket, considering the adjustment for the exemption.	0	No tax or full exemption for the group
		Positive number 0-100	
top_lower_bound	The minimum amount including and above which the top rate for the tax applies to the group, considering the adjustment for the exemption.	0	No tax or full exemption for the group
		Positive number	
fbusiness_exemp	Indicator for the family business to be exempt from taxation.	0	No
		1	Yes
		_na	Not applicable because the tax is not levied
fhome_exemp	Indicator for the family home (i.e. the habitual abode) to be exempt from taxation.	0	No
		1	Yes
		_na	Not applicable because the tax is not levied
note	Note for publication		

A first round of cleaning and standardization enforces basic validity requirements, including the presence of mandatory variables, admissible values, and coherent year ranges. Controlled-vocabulary variables (such as country identifiers and currencies) are systematically validated against reference tables from the project dictionary to ensure cross-dataset comparability and consistent naming conventions.

Subsequent stages address the analytical harmonization of the tax schedules. In cases where a tax is inactive or fully exempt, fiscal parameters are automatically filled according to predefined rules, ensuring internal consistency across variables. Reported tax schedules are then decomposed into numeric components, checked for logical coherence, and adjusted for exemptions or tax credits which are embedded in the schedule structure. Adjacent brackets with identical marginal rates are merged, and the dataset is reshaped so that each row corresponds to a single tax bracket. Finally, general indicators — such as tax type, top marginal rate, and top rate lower bound — are filled where missing, variables are renamed and labeled according to the dictionary, and the fully harmonized dataset is saved in a long format suitable for integration into the main warehouse.

All monetary variables in the database are harmonized following a standardized currency framework defined in the project dictionary. While the Excel is filled with the values as reported in the original source, during the harmonization process the monetary values are converted to local currency units used in the World Inequality Database in 2025 to allow comparability. Automatic warnings flag non-standard or outdated currency codes, while manual validation ensures coherence in cases of monetary unions, dollarized economies, or historical currency changes. For 30 countries (Australia, Austria, Belgium, Chile, Croatia, Cyprus, Czechia, El Salvador, Equatorial Guinea, Finland, France, Germany, Gibraltar, Greece, Ireland, Italy, Jamaica, Lithuania, Luxembourg, Mauritania, Mexico, Netherlands, New Zealand, Norway, Peru, Portugal, Spain, Turkey, Venezuela, Zambia), the sources report tax schedules in a historical national currency in place in a given year (for instance, German Mark in Germany prior to the introduction of the Euro). We convert those historical currency values to the local currency unit by using the fixed conversion rate established at the time of currency exchange in each country. For Barbados, Belize, Bolivia, Chile, Cuba, Guyana, Isle of Man, Somalia, Uzbekistan, and Zimbabwe, for which the sources report the tax schedule in a different currency (not a historical one), we use the market exchange rate to get the national currency. Table D.2 below reports the fixed conversion rates we applied.

D.3 Data Quality Assessment

Data quality is assessed through a combination of automatic and manual checks applied at different stages of the pipeline. Automated verification routines implemented in Stata systematically detect errors and

inconsistencies, such as inadmissible values, negative entries where positive amounts are expected, incoherent combinations of tax status and exemptions, or overlapping information across sources. When multiple sources are available for the same country–year observation, a hierarchical selection mechanism assigns a single reference source based on data completeness, temporal coverage, and preference for legislative material. In cases of disagreement, the most reliable information is retained, while discrepancies are explicitly documented in the notes.

Beyond internal consistency checks, data quality is further evaluated through ex-post validation using cover-

age diagnostics. Country-level and cross-country data coverage graphs are produced to assess the temporal availability of key tax dimensions, including tax status, exemptions, marginal rates, full tax schedules, and revenues. These visual tools support the identification of gaps, inconsistencies, and implausible patterns over time, enabling targeted corrections before release. Together, this multi-layered validation framework ensures that the final Taxes on Wealth v2.0 dataset is internally coherent, transparent in its sourcing decisions, and suitable for comparative and longitudinal analysis. Figure~D.1 illustrates an example of country-level data coverage for Italy.

Figure D.1: Example of country-level data coverage for Italy in the Taxes on Wealth database

D.4 Data Expansion

Version 2.0 of the Taxes on Wealth database substantially expands both the geographical coverage and the temporal depth of the Taxes on Wealth section. The release introduces 31 newly covered countries, accounting for 447 new country-year observations, and extends the historical coverage for 93 countries already included in previous versions, adding 2,017 additional country-year observations.

Table D.3 summarizes all additions introduced in version 2.0 relative to version 1.2.

Table D.3: New countries and extensions of historical coverage in Taxes on Wealth v2.0. The table aggregates additions from record-level differences between versions.

Country	Years

Appendix E

Appendix to the Inheritance Trends Section

E.1 Introduction

This appendix reports the source list and source-level coverage currently available for the Inheritance Trends dashboard data. The tables are generated from the dashboard metadata and the shared dictionary, so they can update as new sources are added to the warehouse.

E.2 Sources Included in the Inheritance Trends Section

Table E.1 lists the sources currently present in the Inheritance Trends dashboard metadata. Source labels and citation keys are taken from the dashboard metadata where available and filled from the dictionary by matching on `Source` where needed.

E.3 Source Coverage

Table E.2 summarizes the country, time, observation, and `varcode` coverage of each source currently present in the Inheritance Trends dashboard data.

Table E.1: Sources in the Inheritance Trends section
